DOCUMENTS IN THIS PRIMER

JESS.....
OPENING UP THE BLACK BOX

APPROACHING JESS

Welcome! We, the authors of JESS, extend greetings to you. May your journey with us be a rewarding one.

WHAT JESS CAN DO FOR YOU

JESS is a large body of computer software and data concerned primarily with the modelling of chemical phenomena in water solutions. It is now the world's largest single electronic source of thermodynamic information relevant to such systems. We seek progressively to extend, manage, check, correct, harmonise **and apply** this material.

Accordingly, you should find that the package offers you a comprehensive, robust and up-to-date thermodynamic modelling facility, which reconciles the significant differences that tend to occur between literature sources. Errors, discrepancies and omissions abound in this area, sometimes even within the most authoritative work. Such mistakes propagate chaotically unless they are well controlled.

Although JESS has many facets, a strong emphasis is placed on the concept of chemical speciation (*i.e.* the identity and relative abundance of different chemical entities which may be present). Speciation is important because it often controls the properties of chemical systems. The behaviour of many biological, environmental and industrial processes depends on the concentration of individual species. These concentrations arise from the thermodynamic equilibria and kinetics of competitive reactions. Knowing only the total amount of each element, in contrast, is much less useful than is often supposed.

However, calculating chemical speciation distributions and, hence, developing a better understanding of chemical system behaviour, is hardly ever straightforward. Digging out a set of equilibrium constants from the literature and simply putting these into a computer program to determine species concentrations under certain conditions is rarely informative, and works only with some well-defined laboratory solutions. Successful thermodynamic modelling of aquatic

"Inside every large program, there is a little program trying to get out."

Hare's Law of Computerdom

Some JESS statistics

546 programs
440,000 lines of code
31,400 literature references

Thermodynamic database:
80,700 reactions
280,000 constants

Physicochemical database:
510,000 values
860 solutes

Solubility database:
127,000 phase records
1500 analytes

systems in general requires much more knowledge and skill. It is critical to appreciate that a single set of numerical results is unlikely to yield the insights you should be seeking.

> "What people misunderstand about Wikipedia and other online resources, and about the wisdom of crowds in general, is that knowledge is about more than assembling a box of factoids or making coin-toss predictions. Facts do not speak for themselves."
>
> Tom Nichols
> *The Death of Expertise* p. 127 (2017)
> Oxford University Press

JESS thus contains a great deal of coded knowledge about chemical speciation, and about the way chemical speciation calculations should best be performed. Its expertise takes the form of programmed algorithms, explicit rules, fuzzy logic and even some Bayesian-type functions. These decision-making techniques assist you with tasks that otherwise would require considerable experience and which, even then, can prove difficult to accomplish reproducibly and without error. Above all, they allow you to explore freely the chemical and numerical complexities in your aqueous systems of interest.

Our overriding objective is to help you model chemical speciation as rigorously as possible by *general* methods. Powerful modelling facilities are needed for the calculation of chemical species concentrations in multicomponent solutions and of physicochemical properties such as solubilities, equilibrium constants, activity coefficients, heat capacities and solution densities. While the JESS databases are much more comprehensive than those of other modelling packages, and are better suited to the requirements of modellers than are the standard literature sources of thermodynamic data, this is only just the start. JESS also offers many computational tools for cross-checking the literature, for testing internal consistency and for trialling various modelling scenarios. These work together with our regular procedures for critical data assessment to ensure ever-improving data coverage and reliability. Even more important, is the assistance you need to tackle a variety of vexing issues which typically arise in thermodynamic modelling studies, as discussed in Chapter 10 of this Primer.

The size and complexity of JESS may seem formidable. **Please do not be put off by this.** You can learn what **you** need to do quite quickly and you can then easily get some useful results. The system is designed to let you progress one simple step at a time.

Of course, much still remains to be done. Full automation of chemical speciation calculations remains a long way off. You will need to make an investment of time and effort to use JESS effectively. However, you should then find JESS to be a powerful tool that can greatly assist you in your aqueous solution chemistry researches.

Thermodynamic Reaction Modelling

In most JESS modelling, the speciation is calculated using known thermodynamic parameters for the relevant reactions in aqueous media. All types of chemical equilibria, including protonation, complex formation, redox, and solubility can be modelled. Variations in the relative amounts of components, ionic strength, temperature and solution pH are fully taken into account. The profile of **all** critically-assessed species is obtained, regardless of how little of each one may be present. The calculations are thus especially useful when systems are not amenable to analytical quantification, either because they are too complex or outside experimental range. Indeed, the models are at their most powerful when predicting the chemical behaviour of multicomponent mixtures.

> "Far better an approximate answer to the right question,
> which is often vague,
> than an exact answer to the wrong question,
> which can always be made precise."
>
> Tukey's Principle
> cited by D.D. Perrin and R.P. Agarwal in
> *Metal Ions in Biological Systems,* Vol. 2, p. 167 (1973)

Since speciation models are thermodynamically based, not empirical, their results are always sound, at least within the limits of the available thermodynamic data and your modelling skills. The insight you can obtain from these models is governed largely by your expertise in assessing the accuracy and applicability of this data and by your imagination in probing the effects of the chemical relationships that operate in the system of interest to you. Unfortunately, the limits of available thermodynamic data often make quantitative calculations problematic. Modelling skills are needed to overcome or bypass the difficulties associated with difficult chemistry and poor or missing data.
Skeleton of newly-discovered dinosaur species reconstructed from two fossils (disputed by some experts)

Physicochemical Property Modelling

JESS also allows you to model a variety of physicochemical properties for electrolytes and (a few) non-electrolytes in bulk aqueous solution. Quantities such as activity coefficients, osmotic coefficients, relative enthalpies, heat capacities, and densities/volumes can be calculated. These models cover wide ranges of temperature, pressure and solute concentrations, typically to 300 °C, 1 kb and solute saturation. Such modelling is based mainly on the well-known Pitzer equations but other theoretical thermodynamic frameworks, including the Hückel equation and Zdanovskii's rule (for electrolyte solution mixtures) are supported.

The Main JESS Databases

A vast number of experimental measurements and compilations of smoothed data have been published in the chemical literature. We are endeavouring to capture these published values (*i.e.* to extract them from their various sources and to store them in computer-accessible form). In addition to the data collection itself, every value is assessed and, where appropriate, used to parameterise our models. In this way, the best possible descriptions of the thermodynamic behaviour for simple aqueous solutions can often be achieved.

The JESS interface for handling the thermodynamic data of chemical reactions is called 'JTH'. The main JTH database, containing chemical reactions and their parameters such as equilibrium constants and reaction enthalpies, is called 'JPD' (for 'JESS Parent Database'). The JESS database of physicochemical property values is called 'FIZ'. The JESS database of solubilities is called 'SOL'. The JESS database of literature references is called 'JLR'. JESS also supports a large database of Pitzer parameters, called 'PTZ'.

ABOUT THIS PRIMER

The purpose of this Primer is to guide newcomers in their initial approach to JESS. It comprises a set of documents that tell you how to use the main JESS facilities.

Most of us are so keen to try out a new software package that we are tempted to do so without first digesting the documentation. After all, we've just gone to considerable expense to obtain it or we've just concluded that it can solve our most pressing problem. We want results. Then we hit a problem and (at best) denounce the package as "not user-friendly".

Accordingly we, as the developers of JESS, make the following plea. **Please take a while (at least an hour) to peruse this Primer thoroughly.** Find somewhere quiet. Browse through each of the documents. Get a feel for the system overall. Establish where the detailed information is provided so that you can find it quickly when you need it. Then, and only then, try out some JESS programs. Also, it is advisable to follow the sequence given in this Primer – you will need to be familiar with all the early concepts when you begin modelling in earnest. Hence, skipping over them now only means you will probably learn about them the hard way! *This is especially true of those details which almost certainly seem least interesting, such as how to manage and edit your computer files.*

We believe that you will familiarise yourself with the JESS system best by using it. Accordingly, a basic approach is adopted in this Primer for each JESS facility that is described. First, we give you a worked example and, then, we provide the essence of what you need to make the facility work. Details are largely passed over. More comprehensive information appears in the interactive help facility and on the website (see below), which you should fully consult for further guidance once you have worked your way through this Primer.

During this introduction, it is important that you explore adventurously. Don't worry about your inexperience - you can't do any damage. The programs chosen to demonstrate JESS are mostly for display and calculation purposes only. They do not alter anything permanently.
Don't worry; be happy!

We have done our best to keep the JESS interface straightforward, consistent and convenient. However, the kinds of tasks we are concerned with cannot be reduced to trivial operations. So, you need to be patient, learn the rules (which are not that numerous) and practice following them.

These Primer documents have been written as independently of one another as possible so that you can concentrate on those which are of most immediate interest to you. But please remember that you must learn to walk before you can start running!

The layout of the Primer is as follows.

- GETTING STARTED - tells you how to run JESS programs and briefly outlines how you should interact with them in general, with some key worked examples, including an initial speciation calculation.

- THE THERMODYNAMIC REACTION DATABASE - describes how you can inspect thermodynamic information (using program VEWJTH).

- THE LITERATURE REFERENCE SYSTEM - describes how you can inspect the information in a JESS Literature database (using program VEWJLR).

- THE PHYSICOCHEMICAL PROPERTY DATABASE - describes how you can inspect the information in the JESS database of physicochemical properties (using program VEWFIZ).

- THE SOLUBILITY DATABASE - describes how you can inspect the information in the JESS database of solubilities (using program VEWSOL).

- THE UNIVERSAL DATASET - describes how you can inspect the information in all the JESS databases combined (using program VEWUDS).

- FILE MANAGEMENT - describes how you use your computer's operating system to organize and store the files you generate in JESS modelling.

- TEXT EDITING - describes how you can prepare and edit data for input to JESS programs (using the JED text editor).

- JESS MODELLING DESIDERATA - provides a short summary of the major issues involved in JESS modelling of chemical speciation.

- EQUILIBRIUM CALCULATIONS - describes how you can perform a simple calculation of an equilibrium distribution (using the sequence of GEM programs).

- WHAT ELSE ? - suggests ways in which you extend your knowledge and use of JESS.

- SUPPLEMENTS - describe how you can access physicochemical property parameter information (using program VEWJAM) and discuss possible future developments.

INSTALLING THE SYSTEM

As far as this Primer is concerned, JESS should already be installed on your computer and you should know how to access it. Either you must have installed the system yourself or have obtained help from someone else who can do so. Detailed instructions on how to install the system are available: look in C:\Jess87\JesDoc\Manuals\Users\Implementation for the documentation. Contact Peter May if you experience any difficulty. Email inquiries can be sent to 'P.May@murdoch.edu.au'.

JESS has been implemented on many computers and under many operating systems. Note, in particular, that the JESS interface has been kept as simple as possible to maximize the number of computer environments that can support JESS, now and in the future.

What To Do If You Hit A Problem With Installation

If you have any difficulty getting started, it will almost certainly be because your instructions have been deficient (!), and you are not set up correctly. It is then a good idea to go through the implementation instructions again carefully to see where you might have been misled! If this doesn't help, try a little investigation to unearth what has gone wrong. Most problems experienced by newcomers to JESS can be traced back to one of three causes:

(a) Your JESS licence is invalid or being implemented incorrectly. Make sure your JESS username and licence checksum are *exactly* as supplied. These must be made available to JESS programs by the operating system, typically *via* so-called 'environment variables' called 'jusr' and 'jchk'. You can display these in your DOS Window with the commands:

> echo %jusr%
> echo %jchk%

You can also check that this data is properly presented to JESS using program TSTSYS.

(b) The program cannot find the files it needs. This may be because the files are not where they should be or because a system-specific mechanism needed to access them is not operational. Make sure your JESS directory structure, and the pointer to it, are properly set up. The pointer

is kept in the environment variable called 'JESS'. You can display this in your DOS Window with the command:

> echo %JESS%

(c) You do not know how to respond to the JESS program prompt. This is the information provided in the next Primer document.

OTHER JESS ASSISTANCE

The purpose of the Primer is to introduce you to the facilities encountered most often by the average person using the system. The programs mentioned are only a few amongst more than 500 in the JESS package. Clearly, there will be further applications of JESS (beyond those dealt with in the Primer) awaiting you. However, you should note that many JESS programs were written for use only by us, the developers of the system. They are not needed to perform speciation calculations; nor are they involved in the processing of data required for such calculations. Details of these other facilities are given in the Developer's documentation.

Another useful facility is the JESS website: http://jess.murdoch.edu.au. This allows you to inspect our databases over the internet (albeit in rather restricted ways) and it also provides certain 'help' documentation on topics beyond those covered in this Primer.

GETTING STARTED

This document begins with what you need to know **before** attempting to develop your own speciation models using JESS. Do not try anything else until you have read this carefully! It has an important worked example which is intended to get you started with a simple chemical speciation calculation.

RUNNING JESS PROGRAMS

JESS consists of a suite of computer programs. There are also some useful facilities based on Excel spreadsheets, which are described later on in this document and elsewhere. How you execute the computer programs we provide is described here for computers with DOS Windows as the operating system.

> "Thoughts are but dreams
> till their effects be tried."
>
> *Rape of Lucrece*
> by William Shakespeare (1564-1593)

Most JESS operations are 'command-driven' (as opposed to the 'point and click' of a graphical interface). This means you must learn the commands and conventions used to control and work JESS. Most people at first find this harder than clicking icons but they succeed with a little patience and perseverance. Once you become familiar with them, command-driven systems are much more powerful and efficient than their graphical counterparts.

Under the Windows operating system, you always work in a DOS window. Set up a short cut for this purpose on your desktop and/or task bar. We recommend (a) a buffer size of 50 and (b) a screen size of 8×12 be set up as defaults.

To begin, focus on two things.

1.   The form of instruction required by the operating system to execute the program - for 'stand-alone' JESS programs, at the DOS prompt (shown as >), you enter:

```
> XQT program-name
```

The DOS-level command XQT (which is not case-sensitive) starts the program. Generally, the program then requires some input from you, either a JESS-level command or something like a database name. You must therefore familiarise yourself with the names of the programs you want to use and with their input requirements. This is illustrated in worked examples below.

2.   The correct places from which to access JESS programs and the computer data files that they require.

Computer files reside in 'directories' or 'folders', *i.e.* named areas of storage, which may hold many files. JESS programs have specific requirements concerning the directories in which their data files are located. Typically, however, you will not need to be aware of the files that you use or their location on the computer. But you will often need to start work in an empty directory/folder so that JESS can build in it some of the files that it will require. Since your modelling results will generally need to be preserved, careful thought early on about the folders you use, their names and structures will be well rewarded.

RESPONDING TO JESS PROGRAMS

Most JESS programs are 'interactive'. This means that you communicate with the program while it is executing. You provide information when prompted and you give it commands to perform various tasks. This does not mean that you have to learn dozens of commands. The commands used throughout JESS are consistent; so once learnt they apply in much the same context when using other programs.

JESS always attempts to protect you from yourself! The programs examine your responses and do their best to diagnose any errors you might make. So don't be too concerned about making mistakes. Don't worry; be happy!

JESS prompts normally end with a colon (:) though a question mark (?) is also sometimes used. If your VDU cursor is positioned just to the right of such a prompt, the program is waiting for you to respond. Anything you then type is only implemented when the |ENTER| key is pressed. Generally this allows you to correct typing mistakes quite easily (provided they are deleted before you press the |ENTER| key).

In an attempt to reduce the amount you have to do, JESS will often display a so-called 'default response' at the end of a prompt (enclosed within < and > characters). Just pressing the |ENTER| key will then provide this default as your response. If the default is unsuitable, you simply type the correct response instead.

As noted above, JESS programs are 'command driven', *i.e.* you choose from a set of commands to tell JESS what to do. These commands can normally be abbreviated, *i.e.* truncated. Usually the first letter of the command will be unique and therefore sufficient. Commands can generally be entered in upper or lower case.

Data required by the programs, other than commands, can also often be abbreviated. Sometimes this involves methods of abbreviation which are more complicated than simple truncation. The Literature-Reference programs employ this kind of special convention - as described later on.

The most important thing for you to remember at this stage is the **Quit** command. Use this to terminate whatever you are doing. In other words, **Quit** can be entered in response to almost any prompt, regardless of what the program is expecting. (The only significant exception to this rule involves the **End** command which is used to terminate some input sequences.) If you are at the top level of command of a program, **Quit** will stop execution (usually after the program has confirmed that you really do want to finish). If you are at a lower level of program input, **Quit** will return you to a higher level of operation. Note that, accordingly, entering multiple **Quit** commands in succession will usually lead to program termination whatever your current status in the program.

You should also note that there two kinds of general assistance available to you when you execute any interactive JESS program. Entering two question marks, **??**, at any prompt will tell you the kind of information which is expected by the program. Many prompts also provide detailed information in response to the **Help** command.

The commands **Quit**, **End** and **Help** can always be entered as just **Q**, **E** or **H,** respectively.

A WORKED EXAMPLE

- Position yourself in an empty 'directory' (folder).

> It is important to do this because it ensures that, no matter what happens, you will not affect anything except the temporary files created during this exercise. At the end of this worked example you will delete everything in your working directory (folder) to leave it exactly as you started. Moreover, if something does go wrong, you can always begin again just by deleting your files and repeating the worked example from scratch.

- Execute program TELSUB.

> **xqt telsub**

It should respond as follows.

```
TELSUB (Version 8.7) JESS copyright (C) 1985-2019
Licensee: Murdoch University
Welcome. Sunday, 10-Feb-19 15:50

Creating Resident Data . . .
```

This message only appears on the first occasion, *i.e.* when your working directory (folder) is empty.

- Immediately **Quit** the program

```
Project title < New Project A > :  Q
```

> This sets up a default model for you, involving a system of calcium carbonate equilibria. You can see what has happened by entering the command **dir** (at the operating system prompt) to list all the files now present in your working directory (folder). You'll be pleased to know that you do not need to understand the file-naming conventions; nor are you likely to ever use them explicitly yourself!

> Later on you will use program TELSUB to specify the starting information required to develop your own speciation models.

● Carefully, and in sequence, execute programs DOSUB, DOLGK, DOBAS and DOQED.

> **xqt dosub**

………

> **xqt dolgk**

……..

> **xqt dobas**

……..

> **xqt doqed**

……..

These programs transform the relevant thermodynamic data, taken from the JESS Parent Database, into the equations which are finally solved (by DOQED). Note the output produced by some of the programs as you go along (represented above as …….) but don't worry about what it means for the time being.

● Execute program VEWQED.

> **xqt vewqed**

It should respond as follows.

```
TELSUB (Version 8.7) JESS copyright (C) 1985-2019
Licensee: Murdoch University
Welcome. Sunday, 10-Feb-19 15:50

```

> This leads to the display of the predominant species. Enter **5** (the default) which specifies that the 5 most predominant species should be displayed. Then nominate the element calcium (enter **Ca**). Inspect the result. Return to the main menu by entering **Q** for **Quit**.

- Explore the output of VEWQED adventurously. You cannot do any damage!

> For instance, select option **6** (from the above menu) to get the 'Saturation State of Solids'. Then, entering **1** for 'All Solids' and 'any' (the default) will display a list of solids, their 'Saturation Indices' (SI) and their relevant solubility products (lg(Ksp).

- Terminate execution (with **Q**, for **Quit** at the QED Command prompt).

- Clean up your directory (folder).

> Delete all files in your working directory (folder) *immediately* on exiting program VEWQED. (In other words, be careful you do NOT move to another location and then delete everything there!)

ON-LINE DOCUMENTATION

A limited amount of information is available on-line (if you have access to the whole of JESS). Specific parts of this documentation are displayed when you enter the **Help** command at the relevant prompts of many JESS programs. In addition, you may browse through the help material, and search for text associated with certain combinations of keywords, using the program HELPER.

Information from HELPER is provided about topics, programs and events. This information HELPER is organized into sections, each of which is located by a **label** (*i.e.* a distinguishing sequence of alphanumeric characters, such as 'T01A'). Simply type any label at the prompt to have the text displayed for the topic concerned. In general, at the HELPER prompt, you start by entering a keyword of interest to you, the program then displays one or more relevant labels, which you can then enter.

Keywords recognised by program HELPER can be any word or phrase that you can think of in connection with the area in which you are needing help. You can enter more than one keyword simultaneously, separated from each other by ' **+** ' (for inclusion) or ' **-** ' (for exclusion). Thus, '**view + database - literature**' finds entries associated with inspecting databases other than literature databases. Labels have the form 'xmny' where x and y are alphabetic letters and m and n are digits. They are displayed alongside the index entries located when you enter recognised keywords.

To summarise: you use the index facility of program HELPER to find out what these **labels** are; by entering keywords for subject of interest to you, you obtain a list of index entries (each with an associated **label**); then, to read the help-text you want, you simply enter any **label** chosen from the displayed list.

So, for example, here is what things look like if you use program HELPER seeking information about the XQT command. The inputs you type are shown in bold (and are rather sparse).

```
> xqt helper

HELPER (Version 8.7) JESS copyright (C) 1985-2019

Welcome. Sunday,  10-Feb-19  7:24

JESS HELP FACILITY
------------------

Enter keywords or subject labels (e.g. T01A), as required.
(Subject labels can be thought of as page numbers of the documentation.)
You can also browse onwards by pressing ENTER at any time.
Further instructions can be obtained by typing H (for HELP).

                  Search for help on <T01A> : xqt

T02X - The JESS command "XQT" (to execute a program)
-------------------------------------------------------------------------------
                  Search for help on <T01A> : T02X

The JESS environment command "xqt" is used to execute a JESS program.
The program in question is specified by name, with the name separated
from the "xqt" by a single space.

In this way you need not be concerned with the executable codes for
all the JESS programs or where they  are located. The paths (and
authorizations to traverse them) are handled transparently. Likewise,
the links between programs and JESS data files are automatically
taken care of (within the JESS environment).

-------------------------------------------------------------------------------
                  Search for help on <T02Y> : q
```

CHEMICAL SPECIATION MODELLING – NEXT STEPS

Two main facilities for chemical speciation modelling are supported by JESS. The first, called GEM (for Generalised Equilibrium Modelling), is used to explore the full complexity of possible chemical interactions in solution. The second, called SRS (for Small Reactive Systems), is still under development; it is used when the system of interest is more straightforward but you seek greater quantitative accuracy. Since the chemical systems covered by SRS are relatively well-defined, particularly regarding the set of chemical reactions which are applicable and how their (conditional) equilibrium constants change, the results are easier to obtain and are more likely to be quantitatively accurate. On the other hand, GEM calculations encompass a far greater number of chemical substances and much larger models.

For now, the GEM calculations are all you should be concerned with. These are described in Primer Documents 10 (MODELLING DESIDERATA) and 11 (EQUILIBRIUM CALCULATIONS).

There are certain things you must know in advance to perform your own GEM calculations. For example, you will soon need to know how to use the JESS editing facilities. These are required to change the program input specifications. All that is needed here is a quick introduction, which is provided below, but full details can be found in Primer Document 8 (FILE MANAGEMENT) and Document 9 (TEXT EDITING). You must also be able to describe to the computer (in the form of JESS programs) the chemical systems of interest to you, particularly regarding their composition and concentrations. This requires an elementary knowledge of JESS conventions, symbols and notation for chemical reactions. You learn about this below and in Primer Document 3 (THE THERMODYNAMIC REACTION DATABASE).

Editing JESS data

JESS supports a line editor for creating and modifying text files. This editor is called JED. Initially you will only need to employ a few, simple editing operations under the control of programs other than JED itself. Note that editing operations are the same throughout JESS, regardless of the program in which they are implemented.

Since JED is a command-driven editor operating on individual lines within files, the line number is generally displayed at the front of each line of text. You can type in line numbers to move around the file or you can locate lines containing particular bits of text. You can, of course, also insert new lines, delete lines that are not wanted, substitute one bit of text for another and cause a whole block of lines to be displayed. These operations are all performed by the appropriate command: **Locate**, **Input**, **Delete**, **Substitute** and **View**. The commands can be abbreviated to just one letter and are not case sensitive.

A particularly useful facility exists to change the text on a particular line. Typing (non-blank) characters directly underneath text that you want to modify imposes these new characters instead of the old ones. Furthermore, there are two 'special characters' (these being | and ~) which enable you to <u>insert</u> or <u>delete</u> characters when they are typed directly underneath the text that you want to modify.

Chemical symbols and notation used by JESS

To describe chemical species and chemical reactions JESS works with a set of symbols (for species) and some rules (for the way chemical reactions must be written).

The symbols for chemical species are easily recognised, the main issues being that the symbols cannot have superscripts or subscripts and that reaction stoichiometry must be described in ways that are general, unambiguous and parsed reasonably easily by the computer.

The building blocks of all JESS symbols for chemical species are called **Primitives**. Primitive species symbols comprise any string of characters which identifies the species, followed by a signed integer whenever the species has an electronic charge. Typical primitives are 'Urea', 'H+1',

'SO4-2', 'Gly-1' and 'EDTA-4' for Urea, Hydrogen Ion (the proton), Sulfate, Glycinate and the EDTA anion (Ethylenediaminetetra-acetate) respectively.

Primitive species symbols can be joined to others by a separating underscore character, _. Thus, 'Gly-1_H+1' for the neutral species Glycine.

Species stoichiometry is indicated by a number in parentheses following the species symbol. Thus, 'Gly-1_H+1(2)' for the protonated form of Glycine. These combined symbols are known as **Composites**. The order of the Primitives in Composite symbols is irrelevant.

Species that are *not* dissolved in water have their phase appended as '(s)', '(l)' or '(g)'. The phase symbol can appear within the Primitive or it can be appended to a Composite. Thus, we have Urea(s), Gly-1_H+1_(s) and H+1(2)_SO4-2_(l).

Worked example – Getting some simple chemical information

Starting in an empty folder, follow the example below. Note that the default response (shown on the prompt within angle brackets, < >, can be selected by simply pressing |ENTER|.

THE THERMODYNAMIC REACTION DATABASE

This document tells you how to access the information in a JESS Thermodynamic Reaction Database. JESS provides many facilities for processing such data but the description here is limited to the way you can inspect an already-existing compilation.

INTRODUCTION TO JTH

The JESS Thermodynamic Reaction Database system, called JTH, provides a powerful and versatile means of storing and retrieving the thermodynamic data associated with chemical reactions. Data in the JESS Parent Database provides the backbone for equilibrium calculations and thus for the determination of speciation. This database has the three-letter identification, **JPD**. Alternatively, if you are working with a JESS equilibrium model, the database is usually called **DBA**.

Initially, you may feel that JTH databases are somewhat more involved than those of certain other programs for chemical speciation modelling. It is therefore important for you also to be aware of the advantages of the approach that has been adopted. Above all, these advantages are directed to the vital needs of chemical modellers. Indeed, the structure of JTH databases, and the JTH facilities for manipulating thermodynamic data, are key mechanisms by which JESS aims to model chemical systems rigorously but yet conveniently.

"Thermodynamics is
the only physical theory of
universal content
which I am convinced
will never be overthrown."

Albert Einstein 1959.
The Thermodynamic Reaction Database 2

Of most significance, JTH does not require the chemical equilibria to be represented in a pre-determined form. Reactions are described entirely generally, without classification of *species either as complexes and components or as metal ions and ligands. There is thus* no restriction on the kind of chemical reaction that can be included in the database. Of particular importance, this means that information can be represented in the database as closely as possible to the way it appears in the primary literature. So the need to transform chemical equilibria and their associated thermodynamic parameters is largely avoided. The introduction of errors is thereby greatly reduced. Further details are given in the MODELLING FACILITIES document of this Primer.

In addition, JTH enables many equilibrium constant values to be associated with each reaction. By weighting every value individually, the database can thus aspire to be both critical and comprehensive. There are many other benefits, including (a) a more practical approach for dealing with changes in conditions such as temperature and ionic strength and (b) a more objective method of reconciling the marked differences that often occur between published parameters from independent investigators.

A WORKED EXAMPLE

- Execute program VEWJTH. It should respond as follows.

        VEWJTH (Version 8.7) JESS copyright (C) 1985-2019
        Licensee: Murdoch University
        Welcome. Tuesday, 12-Feb-19 15:50

- Enter the database name. For example,

        JTH Database name: **JPD** ◄────

    Use **DBA** instead of **JPD** for the database that is used for modelling purposes

- Begin by viewing some data

        JTH Command (H,L,Q,V) <V> : **V**

        View Data, Reaction, Species or I/O-symbol <D> : **S**

        Species e.g. Na+1_Cl-1: **H+1**

            This should evoke a display of the hydrogen ion species. Note the kind of information which is stored - charge, CAS registry number, molecular formula, molecular weight, chemical names, etc.

        Species : **Q**

        JTH Command (H,L,Q,V) <V> : **V**

```
View Data, Reaction, Species or I/O_symbol <S> : D

Reaction : 1
```

> This should evoke a display of the thermodynamic data available for the dissociation constants of water. (By convention, this reaction is entered first.) Note that there are values for the equilibrium constant in log form (lgK) and for ΔH (dH) under various conditions of background medium, temperature and ionic strength. The reference numbers refer to the associated literature-reference database.

- Try entering the same reaction in full form

```
Reaction : H+1  +  OH-1  =  H2O
```

> Spacing is important; capitalisation is not. Blank spaces must surround the equals sign (=) and the plus sign (+) which separates **H+1** and **OH-1**. No spaces should appear in the species symbols (**H+1**, **OH-1** and **H2O**).

- Now try another reaction

> To illustrate this consider, say, the formation of an ML_3 complex by nickel(II) and glycinate. The symbols for these species are **Ni+2** and **Gly-1** respectively. The following illustrates two quick methods for specifying this reaction.

```
Reaction : B130

Symbol for "M" (metal ion) : Ni+2

Symbol for "L" (primary ligand) : Gly-1
```

> This should show the program analysing the symbols you have entered and locating them, assuming you have entered them correctly and that they are in the database you are using.
>
> The program should then show the thermodynamic data for the reaction

```
        3<Gly-1>  +  Ni+2   =   Ni+2_Gly-1(3)
```

- Achieve the same output in another way

```
Reaction : ML3/M.L3
```

> The program should immediately redisplay the data shown above. Note that you do not have to repeat the identification of the metal ion and ligand - these continue to be assumed until you explicitly change them. *The easiest way to make such a change is to append an exclamation mark (!) after the reaction abbreviation. You will then again be prompted for the species symbols.*

- Try this, remembering that casing is not significant in JTH

  ```
  Reaction : B120!

  Symbol for "M" (metal ion) <Ni+2> : Cu+2

  Symbol for "L" (primary ligand) <Gly-1> :
  ```

- Select the default response

  > Enter **Gly-1** to the above prompt simply by pressing |ENTER|. This should now evoke the thermodynamic data for

  ```
  2<Gly-1>  +  Cu+2   =   Cu+2_Gly-1(2)
  ```

- Now try examining the data for glycine protonation

  ```
  Reaction : B12
  ```

  and

  ```
  Reaction : LH2/L.H2
  ```

  have the same effect, showing the overall reaction, whereas

  ```
  Reaction : B11
  ```

  gives the first proton association constants and

  ```
  Reaction : LH2/LH.H
  ```

  gives values for the second.

- Now try something else

  ```
  Reaction : Q

  JTH Command (H,L,Q,V) <V> : L
  ```

- Locate all the reactions involving glycine, copper ions and protons for example

- Select the first item in the menu

      Select one (1:7) <1> : **1**

      Species : **Gly-1 + Cu+2 + H+1**

            Here again spacing is important. Blank spaces surround the
            plus signs (+) separating the species symbols.

      What sort of display? (Full,<Brief>,Quit) : |**ENTER**|

            All the located reactions should thus be displayed. You could note
            the corresponding reaction numbers and later display the associated
            thermodynamic data using the 'view data' command sequence
            shown at the beginning of this example for reaction number 1. (To
            return to the JTH command prompt, you must enter **Q** for **Quit**.)

- Now you can try another kind of search

      Species : **B**

            The **B** stands for **Back**; its purpose is to return the prompt before the
            current one; this is a standard JTH command, which works at many
            prompts. Here, it should cause the locate menu to be redisplayed.

- Choose option 5, 'Species with given name fragment'.

      Select one (1-7) <1> : **5**

      Chemical Name or Synonym : **proton**

            The program should then show the species symbol (H+1) for the
            proton.

      Chemical Name or Synonym : **water**

            The program should now show the species symbol (H_2O) for water
            and, perhaps, for other compounds whose name contains 'water'.

- Terminate execution

      Chemical Name or Synonym : **Q**

```
        JTH Command (H,L,Q,V) <L> : Q

        Confirm Quit <Yes> : Y
```

BROWSING THROUGH THE DATABASE

You can browse through the database using a conventional method of specifying reaction numbers without typing them out in full. By entering certain special symbols, the program can be made to display reactions on either side of the one last shown or to display the reaction last entered into the database. The symbols are as follows:

Symbol	Meaning
<	Reaction number one less than that just shown
>	Reaction number one more than that just shown
*	The last reaction

Using this mechanism, you can easily and rapidly scan through a sequential series of reactions, using just one keystroke to display each one. Type **V**, for View, at the JTH Command prompt and then select, **D**, for Data. Enter any reaction number from **1** to ***** where ***** is the total number of reactions in the database. Thereafter you can simply enter either **>** to display the next reaction (and its data) or **<** to display the previous reaction.

Note that some reactions have more data than can be displayed on the screen at once. The program will suspend output and display the prompt 'Continue? <Y> : '. You can have more of the data shown (*e.g.* by pressing |**ENTER**|) or you can stop it by typing either **N** or **Q**.

BACKGROUND INFORMATION

Chemical species

The concept of a chemical species is fundamental to JTH. It uses information about species to categorize all the thermodynamic data stored by it (so you can easily locate things) and to check your input.

Every species in the JTH database is represented by a symbol. For example, the ion of Zinc(II) has the symbol **Zn+2** (in which, conventionally, the element's chemical abbreviation is followed by the ion's signed electronic charge). When entering JTH symbols you can, in general, truncate them. The programs will request clarification if this creates an ambiguity.

Symbols like **Zn+2** are called 'primitive' to indicate that they are a basic building-block of the database. For convenience, it is also possible to describe species in terms of

combinations of primitive symbols. In such cases, the symbol is referred to as a 'composite'. In constructing a composite symbol, simply append appropriate primitive symbols together, separating them from one another with underscore characters, _.

Chemical reactions

Chemical reactions can be described using these species symbols. Reactions can be written in any form just as long as the principles of conservation of mass and charge are obeyed. In other words, the JTH database does not impose constraints on which species are formulated as reactants and which as products.

Reactions are represented in much the same way as they are in ordinary chemical writing, *i.e.* the symbols of the reactant species appear on the left hand side of an equals sign, =, and the symbols of the products appear on the right hand side. Species on the same side of the equation are usually separated from one another by plus signs, +, but minus is also acceptable, if that happens to be appropriate. Note that in the representation of a chemical equation as just described, the signs =, +, - must always be surrounded by blank spaces. This permits the database programs to distinguish the species occurring in the reaction and not to be confused by the signs (of electronic charge) which occur in species' symbols.

Consider the JESS format for reactions used in the following examples.

```
H+1  +  OH-1  =   H2O

Cu+2  +  2<OH-1>   =   Cu+2_OH-1(2)
```
Here, **H+1**, **OH-1**, **H2O** and **Cu+2** are primitive symbols and **Cu+2_OH-1(2)** is a composite symbol. Note how the non-unit stoichiometry is dealt with, using angle brackets and parentheses.

Some other rules for representing reactions are indicated in the following diagram.

species enclosed in < > if preceded by a coefficient

reactants separated from products by = (note spaces)

water included to achieve
complete mass-balance

Fe+3 + 3<OH-1> = FeOOH(alpha,s) + H2O

real or integer coefficient

plus (or minus) signs surrounded by blanks
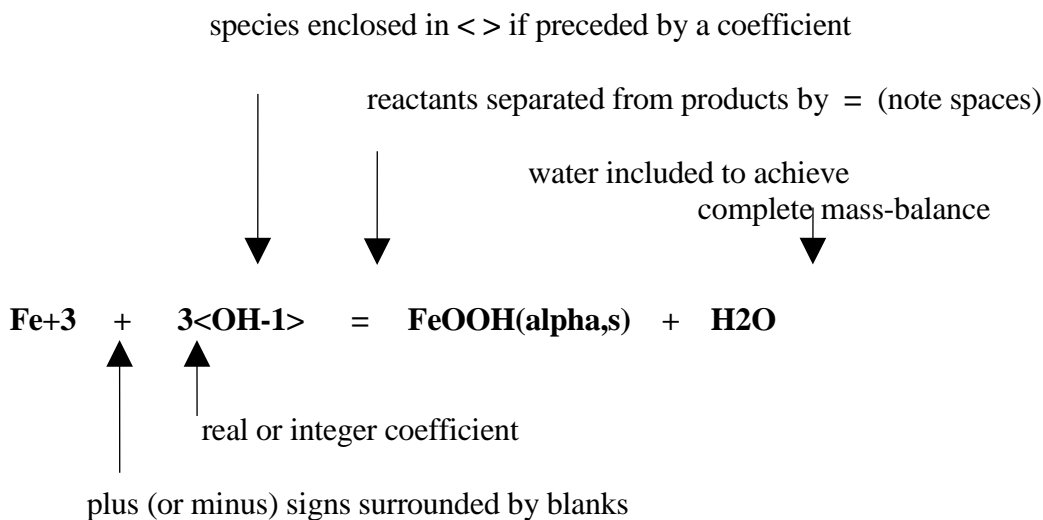

Note in particular the way the *phase* is specified in the species symbol for solid FeOOH. Solid phases always end with an 's' inside the parentheses; individual polymorphs may or may not be indicated, as in Mn(gamma,s) or Mn(s) respectively.

Clearly, this way of specifying reactions requires a lot of care and entering many reactions as described above would be tedious. Unlike the species symbols, the representation or reactions cannot be truncated. Fortunately there are other ways of doing things (as described in the next section) so you will rarely need to construct these reaction specifications in full.

Abbreviating chemical reactions

The simplest way to specify a reaction is to enter its number (if you know it). All reactions in the database are assigned a unique accession number which can be entered at any prompt where a reaction is required.

In addition, there are two abbreviated methods of entering a JTH reaction. Neither are entirely general but they can be used to specify many reactions in a quick and easy way. Both abbreviated methods depend on a preliminary identification of the reactants in terms of a metal ion and one or two ligands. One ligand, called the 'primary ligand' must always be specified. In the first instance, you will be prompted automatically for this information. Thereafter identification of reactants can be changed by appending an exclamation mark, **!**, when you enter the abbreviations.

The first method applies when the reaction is written as a formation reaction, *i.e.* where the product is a single complex and the reactants are the individual, unassociated components of the complex. For example, if the reaction can be written as X + Y = X_Y, then X_Y is said to be the complex and X,Y are its components. The reaction is then specified simply by a **B** (for beta) followed by a string of digits that give the stoichiometry of the complex. In a two component system (*i.e.* with two digits), the order is ligand first, then proton. In a three component system, the digits refer in order to metal, ligand and proton. In a four component system, the metal comes first, then the primary ligand, then the secondary ligand, and the proton last. Proton stoichiometric coefficients can be negative. For example,

by entering   you specify the reaction

  B110   M + L = M_L
  B012   L + H = L_H(2)
  B12   L + H = L_H(2)
  B22-2   2<M> + 2<L> + 2H2O = M(2)_L(2)_OH(2) + 2<H>
  B1210   M + 2<L> + X = M_L(2)_X

The initial letter **B** serves to distinguish these stoichiometries from a reaction number.

In the second method, the letters **M**, **L**, **X**, **H** and the pair **OH** are used to identify components. The reaction is specified by formulating an expression for its equilibrium constant: species are represented by combinations of these letters with digits (giving the

stoichiometry), separated by a period **.** for multiplication of species concentration or by a slash **/** for division. Thus, for example,

by entering	you specify the reaction

ML/M.L	M + L = M_L
LH/L.H	L + H = L_H
LH2/L.H2	L + 2<H> = L_H(2)
LH2/LH.H	L_H + H = L_H(2)
M2L2(OH)2.H2/M2.L2	2<M> + 2<L> + 2H2O = M(2)_L(2)_OH(2) + 2<H>
ML2X/M.L2.X	M + 2<L> + X = M_L(2)_X

Clearly it is easier to use the 'beta mechanism' if it is applicable. Note, however, that the main saving, achieved by both methods, is that (i) symbols do not need to be typed at length and (ii) the variety of symbols and spacing used in the full JTH reaction formulation is avoided.

The MLH mechanism has an additional advantage. By employing it, it is almost always possible to specify reactions using the conventions of Smith and Martell in their volumes of Critical Stability Constants. These can be entered directly in the form they give. Hence, when considering a reaction from a Smith and Martell volume, simply type the MLH abbreviation *without regard to whether digits occur as superscripts or subscripts*. There are exceptions, but this rule works in a very large majority of cases.

USING PROGRAM VEWJTH

This program provides the so-called 'read-only' facilities of the JTH package, *i.e.* it enables you to examine and to search for thermodynamic data but not to do anything that would alter the database.

To begin, the program prompts for the JTH database name. If you are using the JESS Parent Database, enter **JPD**.

After you have entered a valid name, the program is command-driven, meaning that it expects you to enter one of several instructions, indicating what you wish to do. The prompt which is displayed when the program is waiting for one of these commands appears as follows.

```
JTH Command  (H,L,Q,V)  <V> :
```

In response, you can choose to enter any of the commands discussed below. Each of them can be shortened to their initial letter. The letter shown on the prompt between angle-brackets (which, during the session, is usually the previous command entered) is the default command, *i.e.* it is selected simply by pressing the |ENTER| key.

Generally, when the execution of a command is completed (or is terminated prematurely by you), the program will re-issue the prompt, indicating that it awaits new data. You can return to the JTH Command prompt by entering **Quit** or **Q** at any time.

COMMANDS

HELP

This causes the program to display the list of valid commands and a brief explanation. The facility is only an 'aide-memoire'.

QUIT

This tells the program that you wish to terminate the present session. The program requests confirmation of this. Simply pressing |ENTER| (to implement the default **Yes** response) causes the program to halt.

VIEW

You may select one of four basic data types.

I/O symbols

All symbols can be scanned if you press |ENTER| at the 'I/O symbol' prompt. Alternatively you may enter a particular symbol or abbreviation. The symbols displayed will begin with the one entered, if a match is found. You can then display subsequent symbols by repeatedly pressing |ENTER|.

Species

All data associated with a species (such as charge, molecular formula and names) are displayed.

Reactions

A reaction may be entered either as a number or as the complete reaction (discussed previously). The reaction itself (in full JESS syntax) is displayed as well as constants estimated at selected conditions of temperature and ionic strength.

Data

The reaction itself and all data associated with it are displayed. Details are given in the JESS Users Manual. The three-character codes represent the techniques by which the constant and its error were obtained. The numbers within square brackets are literature references; you can obtain the full reference from the associated JLR database (see THE LITERATURE REFERENCE SYSTEM which is documented in this Primer).

LOCATE

Select one of the following options. At this stage you should ignore the others shown on the Locate menu.

- Reactions containing a given species

Entering any species, primitive or composite, will result in ALL the reactions containing that species being displayed. Note that some lists could be very long! However, they are shown one screenful at a time; you can terminate the display by entering **Q** or **Quit**.

You can also search for reactions containing combinations of species. To do this, at the prompt enter your selected list with subsequent species separated from the one before it by a plus, +, (for inclusion) or a minus, - , (for exclusion). The plus and minus signs must have a blank space on either side.

- Primitive species containing a given element

The symbols of all the primitive species containing the chemical element (Fe, N, S, ...) you specify are displayed.

You can also search for primitive species containing combinations of elements. As above, separate the elements by + or - for inclusion or exclusion respectively.

- Species with a given name fragment

The symbols of all the species (primitive or composite) are displayed that have a name which matches the set (or sets) of characters you enter. As above, you can define the search more precisely by entering more than one set of characters separated by + or -, for inclusion and exclusion respectively. Alphabetic casing is not significant. The name fragment(s) you specify can occur anywhere in the name of the species (*i.e.* not just at the start, *c.f.* searching for names using the Query facility). To focus the search it is a good idea to be as specific as possible. For example, entering **eth** + **diam** + **tetra** + **acet** + **acid** is much more informative than entering just **eth** + **diam** or **tetra** + **acid**.

It is better to use short name fragments which you are certain will occur in the name (exactly as you enter them) rather than longer strings which may not match because of differences in punctuation etc. Thus, you should enter **meth** rather than **methylene**. Organic chemical nomenclature, unfortunately, is not as systematic in practice as in theory! Beware, especially, of the positional numbering in names, *i.e.* do not assume that the numbers occur in the name where you think they should. On the other hand, specifying positional numbers by themselves as a separate (included) name fragment will often narrow your search very helpfully.

INFORMATION AT ANY TIME

At odd times and places you may wish to check some detail regarding (i) chemical substance names, (ii) background electrolytes, (iii) solvents (iv) techniques by which a constant has been obtained or (v) weighting of data. This can be done using the 'query facility'.

Queries, made in response to virtually any prompt, take the form: **? XXX** *abbreviation*. For example, you can quickly establish whether chloride is recognized by entering

```
? NAM chloride
```

In general, the **XXX** used above indicates the type of list you wish to inspect and *abbreviation* represents any valid abbreviation for the item of data in question.

The letters **XXX** may be (i) **NAM**, (ii) **BEL**, (iii) **SLV,** (iv) **TEC** or (v) **WGT** corresponding to the kind of data, as described above. Usually, you will shorten these 3-letter codes to their initial character only. Once a match has been found, you can scan through all the following items in the list by repeatedly entering **?N**, **?B** *etc*. (*i.e*. omitting the abbreviation).

Note that abbreviations in JTH are simply the initial characters of the item. They are not case sensitive. You must, however, enter the initial characters of the item exactly as they occur in the list to obtain a match - this includes any punctuation and positional numbering in chemical names. If you are unsure of how a chemical name occurs in the database, but know roughly what it is, you should use the LOCATE command (option 5).

DATABASE MANIPULATIONS

Although we supply large amounts of data as part of the JESS package, you may discover a need to modify things or to insert new information for your own particular purposes. JESS has a large number of programs for these and associated tasks (although, whether you have access to these or not depends on your circumstances).

The most important program in this respect is UPDJTH. This allows you to update any Thermodynamic Reaction Database (hence the abbreviation UPD). The program facilitates the insertion of new thermodynamic data and it allows you to alter data if you have entered it incorrectly. Of course, to modify them you will need 'write-access' to the database files (from the operating system of your computer). Program GBLJTH is also used to modify data when certain systematic changes spanning multiple reactions need to be made.

Database modification introduces a need for so-called 'housekeeping' *i.e*. the internal tidying which becomes necessary to maintain access efficiency. For this purpose, programs such as BLDJTH, MNTJTH and DMTJTH are provided.

It is also likely that you will soon want to transfer data between databases. This may be between your own personal sub-databases or it may involve the exchange of data with

other JESS users. For example, we strongly encourage you to send us newly-measured equilibrium constants or other data which you feel is missing from the JESS Parent Database - this should save you from having to re-enter such data every time you receive a new version of the Parent Database from us. The programs used to exchange JTH data are called PUTJTH and GETJTH; the former writes the data into a set of sequential computer files and the latter loads the information back into a database from such sequential file sets.

JESS also contains programs which check the integrity of your databases and yet others which can list selected information from your databases in various ways.

Full details on how to use these various programs are given in the on-line documentation, available through program HELPER.

✴ ✴

The JTH suite of programs is dedicated to Ruth May
who, with no formal training in chemistry, learned what
needed to be done and entered much of the data into the
'Jess Parent Database'.

✴ ✴

Comments on compiling databases

"It can be verified from personal experience that it is a colossal undertaking to assemble a critically evaluated table of thermodynamic data for inorganic compounds."

Steven G.Bratsch
J. Phys. Chem. Ref. Data, 89, 18, 1.

"Good nature and good sense must ever join;
To err is human, to forgive, divine."

Alexander Pope in 'Essay onCriticism'
cited by HC Helgeson, Am. J. Sci., 82, 282, 1143.
Thermodynamics

"There are ancient cathedrals which, apart from their consecrated purpose, inspire solemnity and awe. Even the curious visitor speaks … in hushed voice. The labor of generations of architects and artisans has been forgotten … seeing only the perfection of the whole … the result of giving ordinary human effort a direct purpose. Science has its cathedrals, built by the efforts of a few architects and of many workers … (such) is the edifice of thermodynamics."

G.N. Lewis and M. Randall
(cited by R.E. Mesmer
in Proc. 5th Int. Symp.
Hydrothermal Reactions,
p. 1)
THE LITERATURE REFERENCE SYSTEM

This document tells you how to access the information in a database of JESS Literature References (JLR). JESS provides many facilities for processing such data but the description here is mostly limited to the way you can inspect an already-existing database. The main JLR database in JESS holds about 30,000 references.

INTRODUCTION TO JLR

The JESS Literature Reference system, called JLR, provides a powerful and versatile means of storing and retrieving literature reference information.

In general, one tends to remember only one or two particular details about any literature reference. One may recall the journal in which it was published or the name of the senior author or some aspect of the subject matter; however, one does not recollect everything, nor even any single thing, consistently. The JLR computer system is designed to store many literature references in a way that permits them to be found even when recollections about them are quite vague.

"Knowledge is power
and the computer is
the amplifier of that power."

E A Feigenbaum   1980

Our approach to the storage and manipulation of literature references differs from that of many other literature database systems in that the items associated with each reference, such as the author names, keywords and publications (books and journals) are treated specifically and not just as character strings in different database fields. This means that it is more efficient as well as being easier to avoid errors due to slight (and often insignificant) differences in the way the item is entered. In particular, JLR uses a method of abbreviation which helps you to pick out the item in question without having to type the whole character string.

The most important use of the JLR subsystem within JESS is to support the management of the literature references associated with our thermodynamic data, especially in respect of the JESS Parent Database, JPD. Details on how to access the JTH subsystem are given in the document in this Primer called THE THERMODYNAMIC REACTION DATABASE.

On the other hand, the JLR facilities are entirely independent of JTH. Some users of JESS software are only interested in JLR! Although the description of JLR provided here deals mostly with how you inspect an already-existing database, you should be aware of the other facilities available for developing and modifying JLR data. A brief outline of these can be found at the end of this document in the DATABASE MANIPULATIONS section.

A WORKED EXAMPLE

- Execute program VEWJLR. It should respond as follows.

  VEWJLR (Version 8.7) JESS copyright (C) 1985-2019
  Licensee: Murdoch University
  Welcome. Wednesday, 12-Feb-19 15:50

  JLR Command (H, L, Q, V) < V > : **V**

  VIEW

- Select the first reference

  Reference: **1**

  > This should evoke a display of the first reference entered into the database. Usually the full reference is followed by details such as the authors, the keywords the heading and the end page. Note the name of an author. For the purpose of this example, say this is **Bloggs GN**.

- Return to the top level of command

  Reference: **Q**

- Then try the Locate function

  JLR Command (H, L, Q, V) : **L**

- Select to search by Author

  Type of search? (A, K, P, C, +, - / H, Q) ·< A > : **A**

  Author : Bloggs GN

  > The program should locate **Bloggs GN** (you should use the author name noted above). If this fails, you have almost certainly not entered the name exactly as it appeared above. Capitalization is important here. If more than one reference is found for the author you have chosen select a Brief display and, if necessary, page through the list thus displayed.

  Type of search? (A, K, P, C, + , - / H, Q) < A > : **Q**

- Terminate execution

  JLR Command (H, L, Q, V) <1>:**Q**

  Confirm QUIT? (<YES >, NO) **Y**

  > Note that in this example all responses were entered explicitly (*i.e.* defaults were not used). In practice you would normally just press |ENTER| when the default displayed by the program was, in fact, the option you wanted. This was the case, for instance, on the first occasion that the JLR command prompt appeared (the default response, <V>, could have been invoked). Also note that in practice one rarely needs to type out responses such as the author name in full. You could, for example, abbreviate by entering just the uppercase letters, *i.e.* **BGN** for **Bloggs GN**.

- Try the example again.

  > This time use default responses where appropriate and abbreviate the author name. Remember to enter **Q** for **Quit** if you get into any difficulty.

BROWSING THROUGH THE DATABASE

For convenience, it is possible to use a special convention to specify reference numbers without typing them out in full. By entering certain special symbols, the program can be made to display references on either side of the one last shown or to display the reference last entered into the database. The symbols are as follows:

Symbol	Meaning
<	Reference number one less than that just shown
>	Reference number one more than that just shown
*	The last reference

Using this mechanism, you can easily and rapidly scan through a sequential series of references, using just one keystroke to display each one. Beginning at the JLR Command stage, one presses the |ENTER| key to invoke the **V**iew option and then enters, say, **1** for the first reference. Thereafter one simply enters > to display subsequent references.

USING PROGRAM VEWJLR

This program provides the so-called 'read-only' facilities of the JLR package, *i.e*. it enables you to examine and to search for references, but not to do anything that alters the database.

The program is command-driven, meaning that it expects you to enter one of several instructions, indicating what you wish to do. The prompt which is displayed when the program is waiting for one of these commands looks like this.

> JLR Command (H,L,P,Q,V) <V> :

In response, you can choose to enter any of the commands discussed below. Each of them can be shortened to their initial letter. The letter shown on the prompt between angle-brackets (which, during the session, is usually the previous command entered) is the default command, *i.e*. it is selected simply by pressing the |ENTER| key.

Generally, when the execution of a command is completed (or is terminated prematurely by you), the program will re-issue the JLR Command prompt, indicating that it awaits a new instruction. Otherwise you can return to the JLR Command prompt by entering **Quit** or **Q** at any time.

COMMANDS

HELP

This causes the program to display the list of valid commands. The facility is only an 'aide-memoire'.

QUIT

This tells the program that you wish to terminate the present session. The program requests confirmation of this. Simply pressing |ENTER| (to implement the default **Yes** response) causes the program to halt.

VIEW

All the details in the database associated with each reference can be easily displayed. The **V**iew command enables you to select references by specifying their identifier (see below). You may supply either the reference string (in full or abbreviated) or its unique accession number or its 'universal identifier'. If you do not know the reference well enough to specify it in one or other of these ways, you will need to find it using the **Locate** command described later on.

When you are finished with VIEW, type **Q** for **Quit** to return to the JLR command prompt.

LOCATE

The **L**ocate command enables you to search for those references in the database associated with particular publications, authors, keywords or cross-references.

Once you enter the **L**ocate Command, you will be asked about the type of search you require. You can then enter one of the permitted codes: **A** for authors, **K** for keywords, **P** for publications, **C** or **R** for a cross-reference, **Q** to abort the search or **H** for some limited help.

Once the kind of search is established, the program will prompt for the particular author, keyword, etc. All references which have been entered with that item will then be located.

References can be shown in full, using the same display as the **View** Command, or in brief. In the latter case, only the reference identifiers and its unique accession number are seen. To prevent information scrolling off the top of the VDU screen, the program interrupts the display of references, requesting you to press |ENTER| when you are ready to continue. Actually, you have three options: (i) press |ENTER| to have the next reference or references displayed, (ii) type **Quit** to abort the search or (iii) type a year of publication, thereby causing the program to skip over references until the search reaches one published in the given year. In the latter case, note that since the references are output in reverse chronological order, entering a year later than that of the last-displayed reference has no effect and entering a year prior to the earliest reference located by the search causes the display to terminate, *i.e.* a return to the JLR command prompt.

When you are finished with LOCATE, type **Q** for **Quit** to return to the JLR command prompt.

PINPOINT

The **P**inpoint command allows you to specify one or more 'name-stems' (i.e. just the initial part of each author name) so that you can **find all references in common to those authors**. Every author associated with each name-stem is included.

When you are finished with PINPOINT, type **Q** for **Quit** to return to the JLR command prompt.

SPECIFYING JLR IDENTIFIERS

References

All references are specified in the following way.

The name of the publication is placed first, followed by a comma. (The publication named may be either a book or a journal/periodical; the name may, itself, contain embedded commas and it may be abbreviated, as described later.)

The year of publication, is placed next, either in full, *e.g.* **1950**, or just as the last two digits, *e.g.* **50**.

For a book this is all that need be specified.

For a chapter in a book, a comma is appended, followed by the chapter's first-page number.

For a journal article, the volume number and first page are appended separated by commas. The volume field, but not the page field, may be null. Spaces around the year, volume and page are not necessary and, if present, are ignored. Examples of valid journal names are given later.

Fictitious examples of typical reference identifiers are:

The Double Helix, 1961	◄——— book
Physiological Chemistry, 1976, 157	◄——— chapter
Nature, 1953, 171, 737	◄——— article
Report No. EPA/600/3-86/-023, 1986	◄——— report
Summer Comput. Simul., Conf. Proc., 1984, 563	◄——— contribution in conference proceedings

Note that journal part/issue numbers are usually redundant and so are generally omitted. However, they may sometimes appear in parentheses following the volume number.

Authors

Most references have an associated list of authors. Each name is stored by the JLR system individually. By convention, you specify author names according to the following format:

(i)   Family names are placed first, <u>suitably capitalised</u>; family names comprising more than one word are typed as such.

(ii)   Initials, again capitalised as required, are placed next, separated from the family name by a blank space; no spaces or periods may be included in the string of initials but other punctuation is acceptable as necessary.

(iii)   Authors can be entered in an abbreviated form as described later.

Fictitious examples of typical author names are:

Watson JD
Crick FHC
Bragg W_Jr.
van der Merwe KJ
Conference Management Committee

Publications

Book names are generally stored in full; journal names are stored in the form recommended by IUPAC. Both can be abbreviated by you, as described later.

Examples of typical publications are:

Talanta
J. Chem. Soc., Dalton Trans.
Light Metals
Sov. J. Non-Ferrous Met.
Tsvet. Metall.

Keywords

Keywords are stored in full.

Examples of typical keywords are:

Speciation
Transition Metals
Equilibrium Constant
Iron
Redox (Potentials/Reactions)
Natural Waters

Cross-References

References can be associated with one another. This is useful in some particular but fairly infrequent circumstances. In the JPD thermodynamic database they are used to indicate either that the same literature article appears as two, or more, references (as when it is published in different languages) or that the publications deal with the same thermodynamic data. You are advised not to worry about this until you have more experience.

LOCATING COMBINATIONS OF JLR IDENTIFIERS

In addition to the PINPOINT command for authors (see above), you can use the LOCATE command to find references that match a combination of criteria.

You do this when prompted for

Type of Search? (A, K, P, C, + , - / H, Q) :

by entering <u>more than one</u> of the codes, **A**, **K**, **P** or **C** separated by **+** or **-** .

Here, **+** means include and **-** means exclude.

For example: Entering

$$\mathbf{A} + \mathbf{A} + \mathbf{K} - \mathbf{K}$$

will permit you to specify two authors and two keywords. The references then displayed will be those associated with both authors and the first keyword, except that if any are also associated with the second keyword they will be excluded, *i.e.* not displayed.

ABBREVIATION RULES

It is generally possible for you to specify an item of data without having to type it in full. Instead, you only have to enter an abbreviation, formulated in one of several ways as follows.

Abbreviations for References

Reference identifiers can be abbreviated simply by leaving off a trailing part of the identifier. In the limit, only the publication name and the year of publication have to be entered.

For example, the reference **Talanta, 1985, 32, 483** can be selected by entering the partial specifications **Tal, 85** or **Tal, 85, 32** instead of (and as well as) the full identifier. If you enter an abbreviation that matches more than one reference, a menu will be displayed and you will be asked to select the particular reference you require.

We also adopt an important and powerful method of abbreviating references based on a so-called JESS 'universal identification code' (UID). This conventional system has the format 'YYZZZ' where 'YY' represents the last two-digits of the year of publication (*e.g.* '98' for 1998 and '00' for 2000) and 'ZZZ' represents the family name (or names) of the author(s). The first letter of each author's family name is always used and capitalised regardless of its actual case (*e.g.* van't Hoff is 'V' not 'H'). With single authors, the first uppercase letter is followed by two lowercase letters from the family name. In the case of two authors, use an uppercase letter and a lowercase letter from the first author and an uppercase letter from the second author. With three or more authors use uppercase letters from the first three authors (only).

For example, the book 'Electrolyte Solutions' by R.A. Robinson and R.H. Stokes that was published in 1959 would be cited as '59RoS'. If you follow these rules you will find that they provide a highly efficient way to specify literature references. If you enter a UID that matches more than one reference, which happens occasionally, JLR will prompt you with the available possibilities.

Other Abbreviations

Other data items, namely author names, publications and keywords can also be abbreviated. In these cases, the rules are: (i) that any trailing part of the name may be omitted, (ii) only those names which match the pattern of uppercase letters supplied are considered - lowercase letters and punctuation symbols can thus be omitted from the given abbreviation.

For example, the abbreviation **EM** would match the keyword **Empirical Methods** whilst **EC** would match **Equilibrium Constant**.

Usually, if more than one existing item matches a supplied abbreviation, the various possibilities are displayed (on a menu) and you are told to resolve the ambiguity by selecting the one required. For example, the abbreviation **EM** would also match **Experimental Methods**, **Electrochemical Methods** and **Environmental Models**. So, if this were entered, the program would need to determine from you which particular keyword is intended.

Searching for items by abbreviation can be speeded up by supplying more lowercase letters. For example, if the JLR system contained many keywords beginning with E, it might take significantly longer to locate **Environmental Models** if you entered the abbreviation **EM** rather than **EnvM**.

It is worthwhile taking a little time to familiarize yourself thoroughly with this abbreviation mechanism. Once you are familiar with it you will find that it is a very convenient way of specifying information for the computer, with a minimum number of keystrokes. The price we pay, however, is that searches for authors, publications and keywords are case-sensitive.

INFORMATION AT ANY TIME

At odd times and places you may wish to check what publications, authors, or keywords exist in the database. This can be done using the 'query facility'.

Queries, made in response to virtually any prompt, take the form: **? XXX** *abbreviation*. For example, **? PUB Tal** could be entered to ascertain whether the journal Talanta was in the database's list of publications. The question mark, occurring as the first character of the response, signifies that a query is being made. The letters **XXX** represent the kind of data item that is concerned; this may be **PUB** for publications, **AUT** for authors, **KEY** for keywords and **REF** for references - each of these three-letter codes can be shortened to their first character; *abbreviation* represents any valid abbreviation, as described above. Note that the blank space between the question mark and the code can be omitted but that the space between the code and the abbreviation cannot, *e.g.* **?P Tal** performs the same search for Talanta as **? PUB Tal**.

In order to scan through the list of existing entries without having to formulate abbreviations to match those items which are present, the query facility displays the first ten items following the first match found (rather than just those fitting the given abbreviation). Once a match has been found, you can list all following items by repeatedly entering **?P**, **?K** etc. (*i.e.* omitting the abbreviation).

DATABASE MANIPULATIONS

In addition to VEWJLR, there are many other JLR programs. Most of these are used for building Literature Reference databases. The insertion of new reference entries and their alteration, if necessary, is performed using UPDJLR. Database modification introduces a need for 'housekeeping', i.e. the internal tidying which becomes necessary to maintain access efficiency. For this purpose, programs such as BLDJLR, MNTJLR and DMTJLR are provided.

A useful JLR facility enables you to print out literature references in any desired format. This can be useful when you are preparing a manuscript for publication. This is accomplished by the program FMTJLR. The instructions which FMTJLR uses to prepare its output involve a number of conventions which you must be familiar with before you try to use the program. The details of this are given in the User's Manual.

It is also possible to transfer literature references between databases. This is accomplished by the programs PUTJLR (to export the information, creating a sequential file of data) and GETJLR (to import data from such a sequential file).
THE PHYSICOCHEMICAL PROPERTY DATABASE

This document describes how to access the information in the JESS physicochemical property database (FIZ). The FIZ database of JESS currently holds almost 500,000 data values for nearly 60 physicochemical properties of over 800 solutes taken from more than 1,250 literature references. Numerous facilities within JESS are used to process such data but the focus in this document is largely confined to how you can inspect all this information.

INTRODUCTION TO FIZ

The JESS Physicochemical Property Database system, called FIZ, provides a means of storing and retrieving the physicochemical property data associated with aqueous binary (one solute plus water) and ternary (two solutes plus water) solutions. Most of the data concern simple electrolyte solutions, such as NaCl(aq) or KOH(aq). The general idea is to link the stored values for recognised solution properties to the particular (bulk) solute or solutes defining the solution and to the well-defined composition, temperature and pressure.

> "The greatest obstacle to discovery is not ignorance – it is the illusion of knowledge."
>
> Daniel Boorstin,
> 12th Librarian of the
> United States Congress.

The FIZ database stores physicochemical property values from the chemical literature. Examples of the type of properties that are stored in the database include activity coefficients, enthalpies, heat capacities and densities. A comprehensive list appears below. Program VEWFIZ allows you to see (a) the raw values and the corresponding literature reference(s) for a specified solute, (b) unified values, i.e. all represented in a standard, common unit and (c) converted values for different but equivalent properties, such as solution density and apparent molar volumes.

In most cases, FIZ solutes are (strong) electrolytes. These electrolytes are specified by a combination of a cation and an anion (in the form of their JPD symbols) separated by a forward slash symbol, '/'. Electrolytes are always assumed to be electroneutral; in other words, the stoichiometry of the two aqueous ionic species is determined implicitly. For example, NaCl(aq) is referred to as 'Na+1/Cl-1' and $MgCl_2$(aq) is referred to as 'Mg+2/Cl-1'. Certain non-electrolytes, such as 'Glucose', are also recognised. Solution mixtures are specified by two solute symbols joined by ' + ' (with surrounding spaces). For example, the mixture {NaCl + KCl}(aq) is indicated by 'Na+1/Cl-1 + K+1/Cl-1'.

Of particular note is that the database contains both values derived from experimental measurements (that we call 'primary' data) and the results of models based on smoothing or regressing experimental information (which we call 'secondary' data). Including both kinds of

property values has a number of benefits, especially for the purposes of characterizing solutions for which primary data are difficult to obtain from the literature (whether due to age, language or some other obstacle) and identifying erroneous data. All data in the FIZ database have been assessed and assigned weights based on their relative reliability. Values that we reject are indicated by weight zero. Other data are weighted on a scale from 1 (low reliability) to 9 (highest reliability).

A worked example of how to use program VEWFIZ appears below. It is also possible to display graphically key sets of FIZ data using an Excel spreadsheet and our so-called '8-ball' facility, the latter being provided as an Excel macro within JESS. To get this working, consult the documentation provided in C:\Jess85\JesDoc\Manuals\Developers\Excel Interface. Two illustrations of such graphs follow. The data points shown in red have been rejected by us (i.e. given zero weight).
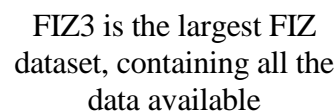

Full documentation is available for the FIZ interface, including lists of the recognised physicochemical properties and the available solutes (with their respective symbols) - see program HELPER to locate this documentation. A short summary is also provided below under 'BACKGROUND INFORMATION'.

A WORKED EXAMPLE

- Execute program VEWFIZ. It should respond as follows.

    VEWFIZ (Version 8.7) JESS copyright (C) 1985-2019
    Licensee: Murdoch University
    Welcome. Sunday, 10-Feb-16 14:49

    FIZ3 is the active dataset   ←-------------   FIZ3 is the largest FIZ dataset, containing all the data available

- Begin by viewing some data

    FIZ Command (C,H,L,Q,S,U,V,W) <V> : **V**

    Solute(s) <Na+1/Cl-1> : **K+1/Cl-1**

    Physicochemical Property : **OC**
    > Osmotic Coefficient

    Lower temperature [C] <0.0> : **10**
    Upper temperature [C] <325.0> : **20**

    Lower pressure [bar] <1.0> : **1**
    Upper pressure [bar] <120.51> : **1**

    Lower concentration [m] <1.0E-4> :
    Upper concentration [m] <8.515> : **3**

    Reference <any> :

        This should evoke a display of values of the osmotic coefficient of aqueous potassium chloride solutions from (10 to 20) °C in the concentration range up to 3 mol kg^{-1}. Note the kind of information which is stored – property value, concentration of the solute as published, concentration in molality, JLR reference number, etc. Press |ENTER| when 'More' is onscreen to view more database records, or type **Q** to return to the main prompt.

The Physicochemical Property Database 4

FIZ Command (C,H,L,Q,S,U,V,W) <V> : **U**

Solute(s) <K+1/Cl-1> : **Mg+2/NO3-1**

Physicochemical Property : **VM**
> Apparent Molar Volume

Lower temperature [C] <0.0> : **25**
Upper temperature [C] <150.0> : **25**

Lower pressure [bar] <1.0> : **1**
Upper pressure [bar] <4.76159> : **1**

Lower concentration [m] <0.0> :
Upper concentration [m] <17.3376> : **4**

Reference <any> :

> This should evoke a display of the apparent molar volume values at 25 °C,
> including those that have been converted from related properties, such as the
> absolute density. Note that the values are converted to a common unit and the
> original property type is also shown.

- Try locating information for a particular solute

    FIZ Command (C,H,L,Q,S,U,V,W) <V> : **L**

    Available options. Search for:

    1. Solute data
    2. Species data
    3. Physicochemical property data
    4. Reference data
    5. Solute symbols

    Select one (1-5) <1> : **1**

    Solute(s) <Na+1/Cl-1> : **Na+1/Cl-1 + Mg+2/Cl-1**

    > This should evoke a listing of the different properties for which data are
    > available, including a summary of the ranges of pressure, temperature and
    > concentration, and the number of data points.

- View data for a ternary solution

    FIZ Command (C,H,L,Q,S,U,V,W) <L> : **V**

    Solute(s) <Na+1/Cl-1 + Mg+2/Cl-1> :

Physicochemical Property : **AC**
> Mean Activity Coefficient
Subject <Na+1/Cl-1> : **Na+1/Cl-1**

A subject is required for some physicochemical properties (see the bolded entries in the table of properties in this document). In the case of mean activity coefficients, the property values refer to only one solute. For this example, either 'Na+1/Cl-1' or 'Mg+2/Cl-1' can be specified.
After entering the limits of temperature, pressure and concentration the relevant data will be listed.

BACKGROUND INFORMATION

Solutes

Electrolyte solutes are denoted by 'Cation/Anion' where the cation and anion names have the same form as recognised by JPD.

The following cations are recognised:

H+1	Li+1	Na+1	K+1	Rb+1	Cs+1	H+1_NH3	Me4N+1	Et4N+1
Bu4N+1	Al+3	Ba+2	Cd+2	Ca+2	Cr+2	Cr+3	Co+2	Co+3
Cu+2	Fe+2	Fe+3	La+3	Pb+2	Mg+2	Be+2	Mn+2	Hg+2
Ni+2	Ag+1	Sr+2	Pr4N+1	Tl+1	UO2+2	Zn+2	Th+4	Nd+3
Sm+3	Eu+3	Gd+3	Sc+3	Y+3	Ce+3	Pr+3	TiO2+2	

The following anions are recognised:

OH-1	F-1	Cl-1	Br-1	I-1
NO3-1	ClO4-1	SCN-1	CO3-2	SO4-2
Acetic-1	Al+3_OH-1(4)	AsO4-3	B(OH)4-1	BrO3-1
ClO3-1	CrO4-2	CN-1	Cr2O7-2	H+1(2)_PO4-3
Formic-1	H+1_CO3-2	H+1_SO4-2	IO3-1	NO2-1
MoO4-2	H+1_PO4-3	Oxalic-2	MnO4-1	PO4-3
Phthalic-2	P2O7-4	SiH2O4-2	CF3SO3-1	Propanoic-1
AsO3-3	S2O3-2	Oxine-1	Fe+2_CN-1(6)	Fe+3_CN-1(6)
Succinic-2	H+1_Succinic-2	Malonic-2	H+1_Malonic-2	Benzoic-1

The recognised non-electrolytes are:

H2(g)	O2(g)	N2(g)	CO2(g)	H2O2(g)
SO2(g)	H2S(g)	NH3(g)	Hg(g)	Glucose
Sucrose	Mannitol	Sorbitol	Xylitol	Urea
Ethanol	Glycerol			

The Physicochemical Property Database 6

Physicochemical properties

Properties are generally designated by 2-letter codes. The property names and their codes are:

Property Name	Unit	ID
Mean Activity Coefficient	unitless	**AC**
Single Ion Activity Coefficient	unitless	**AI**
Mean Activity Coefficient Ratio	unitless	**AR**
Water Activity	unitless	AW
Boiling Point Elevation	C	BE
Boiling Point	C	BP
Isobaric Molar Solution Heat Capacity	J/(K.mol)	CI
Apparent Molar Heat Capacity, Cp	J/(K.mol)	**CP**
Volumetric Heat Capacity Quotient	J/(K.cm3)	CQ
Specific Heat	J/(K.g)	CS
Apparent Molar Heat Capacity, Cv	J/(K.mol)	**CV**
Standard Molar Heat Capacity Offset	J/(K.mol)	**CZ**
Absolute Density	g/cm3	DA
Relative Density Difference	g/cm3	DD
Specific Gravity	unitless	DQ
Apparent Molar Expansivity	/kK	EM
Expansivity	/kK	EX
Freezing Point Depression	C	FD
Freezing Point	C	FP
Molar Excess Gibbs Energy	kJ/mol	**GX**
Standard Molar Gibbs Energy Offset	kJ/mol	**GZ**
Apparent Molar Relative Enthalpy	kJ/mol	HA
Apparent Molar Enthalpy of Dilution	kJ/mol	HD
Molar Enthalpy of Mixing	kJ/mol	HM
Apparent Molar Enthalpy of Solution	kJ/mol	**HS**
Molar Excess Enthalpy	kJ/mol	**HX**
Isopiestic H_2SO_4 Concentration	m	IA
Isopiestic $CaCl_2$ Concentration	m	IC
Isopiestic LiCl Concentration	m	IL
Isopiestic $MgCl_2$ Concentration	m	IM
Isopiestic KNO_3 Concentration	m	IN
Isopiestic KCl Concentration	m	IP
Isopiestic NaCl Concentration	m	IS
Isothermal Compressibility	/GPa	KI
Apparent Molar T-Compressibility	cm^3/(mol.bar)	**KT**
Apparent Molar S-Compressibility	cm^3/(mol.bar)	**KS**
Isentropic Compressibility	/GPa	KY
Osmotic Coefficient	unitless	OC
Osmotic Pressure	Pa	OP
Partial Molar Solvent Heat Capacity	J/(K.mol)	PB
Partial Molar Solute Heat Capacity	J/(K.mol)	**PC**
Harned Cell Potential Difference	V	PD
pe	unitless	PE
Concentration Cell Potential Difference	V	PG
pH	unitless	PH
Partial Molar Solute Enthalpy	kJ/mol	**PQ**

Partial Vapour Pressure	Pa	**PP**
Partial Molar Solvent Enthalpy	kJ/mol	PR
Partial Molar Solute Entropy	J/(K.mol)	**PS**
Partial Molar Solvent Entropy	J/(K.mol)	PT
Partial Molar Solute Volume	cm3/mol	**PV**
Partial Molar Solvent Volume	cm3/mol	PW
Sound Velocity Difference	cm/sec	**SD**
Solubility / Saturation Limit	m	**SL**
Sound Velocity	m/sec	SV
Molar Excess Entropy	J/(K.mol)	**SX**
Specific Volume	cm3/g	VD
Apparent Molar Volume	cm3/mol	VM
Vapour Pressure	Pa	VP
Molar Excess Volume	cm3/mol	**VX**
Standard Molar Volume Offset	cm3/mol	**VZ**

As already noted, instructions on how to implement the '8-ball' facility within Excel spreadsheets can be found in \Jess85\JesDoc\Manuals\Developers\Excel Interface.

You can change the FIZ dataset accessed by VEWFIZ by typing 'gofiz1', 'gofiz2' or 'gofiz3' at the command prompt of the JESS environment DOS-Window. FIZ dataset 1 refers to data mostly taken directly from the chemical literature; dataset 2 refers mostly to values we have estimated; dataset 3 is the combined set of 1 and 2.

THE SOLUBILITY DATABASE

This document describes how to access the information in the JESS Solubility database (SOL). SOL currently holds almost 5,000 datasets with over 75,000 phase records from almost 600 literature references.

INTRODUCTION TO SOL

The JESS Solubility Database, called SOL, stores the conditions of pressure, temperature and composition under which solubility and other specified, measurable properties of aqueous solutions have been quantified. In particular, the SOL system records physicochemical properties of many dissolved systems in terms of given overall concentrations of well-defined substances in the aqueous phase. When non-aqueous phases exist in (thermodynamic or metastable) equilibrium with an aqueous solution, these data define the regions of thermodynamic stability, and hence the solubilities, of each given phase.

> "When a thing is labelled 'complex', that's just a roundabout way of saying you're not observant enough to understand it."
>
> A. Lee Martinez,
> *In the Company of Ogres*.
> Tor Books, 2007

The general idea is to store literature data regarding thermodynamic properties of chemically reactive systems (especially solubilities) in a deliberately general way and to have a variety of computational mechanisms for finding and representing such data. Chemical reactivity is the key feature that distinguishes SOL data from data stored in the FIZ database. However, to some limited extent the SOL and FIZ systems overlap: FIZ has more flexibility regarding property types and units and it is better at dealing with two-dimensional tables of data; SOL has much greater flexibility regarding solution composition, which is specified using JTH symbols.

The Solubility Database is still in an early stage of development. To date, coverage of the relevant literature remains modest. We hope to grow the database considerably in the next few years.

USING PROGRAM VEWSOL

This program provides the so-called 'read-only' facilities of the SOL package, *i.e.* it enables you to examine and to search for references, but not to do anything that alters the database.

The program is command-driven, meaning that it expects you to enter one of several instructions, indicating what you wish to do. The prompt which is displayed when the program is waiting for one of these commands looks like this.

SOL Command (H,L,Q,S,U,V) <S> :

In response, you can choose to enter any of the commands discussed below. Each of them can be shortened to their initial letter. The letter shown on the prompt between angle-brackets (which, during the session, is usually the previous command entered) is the default command, *i.e.* it is selected simply by pressing the |ENTER| key.

Generally, when the execution of a command is completed (or is terminated prematurely by you), the program will re-issue the SOL Command prompt, indicating that it awaits a new instruction. Otherwise you can return to the SOL Command prompt by entering **Quit** or **Q** at any time.

COMMANDS

HELP

This causes the program to display the list of valid commands. The facility is only an 'aide-memoire'.

QUIT

This tells the program that you wish to terminate the present session. The program requests confirmation of this. Simply pressing |ENTER| (to implement the default **Yes** response) causes the program to halt.

VIEW

All the details in the database associated with each reference can be displayed. The **V**iew command enables you to select datasets by specifying their identifier (see below). You will generally need to find the dataset you want by using the **Locate** command described next.

When you are finished with VIEW, type **Q** for **Quit** to return to the SOL command prompt.

LOCATE

The **L**ocate command enables you to search for those datasets in the database associated with particular elements, physicochemical property, keyword, JTH primitive symbol, JTH species or literature reference.

When you are finished with LOCATE, type **Q** for **Quit** to return to the SOL command prompt.

SIZE

The **S**ize command displays the current SOL database statistics.

UNIFY

The **U**nify command displays data values in user-specified concentration units.

When you are finished with UNIFY, type **Q** for **Quit** to return to the SOL command prompt.

A WORKED EXAMPLE

● Execute program VEWSOL. It should respond (more or less) as follows.

```
VEWSOL (Version 8.7) JESS copyright (C) 1985-2019
Licensee: Murdoch University
Welcome. Sunday, 10-Feb-19 13:48
```

● Begin by searching for some data

```
SOL Command (H,L,Q,S,U,V) <L> : │ENTER│

Type of search? (E,F,K,P,R,S,+,- / H,Q) <S> : K
Keyword : Gypsum

     This searches for all sets of data with 'Gypsum' as a word in their title.

What sort of display ? (Full,<Brief>,Quit) : │ENTER│

Set #      Title
-----------------------------------------------------------------------
 433    Calcium Sulfate (Gypsum) Solubility in H+/Li+/ClO4-
 435    Calcium Sulfate (Gypsum) Solubility in MgCl2
 436    Calcium Sulfate (Gypsum) Solubility in Na+Mg Chloride
 437    Calcium Sulfate (Gypsum) Solubility in Na+Mg Chloride
 445    Calcium Sulfate (Gypsum) Solubility in NaCl Soln.
 446    Calcium Sulfate (Gypsum) Solubility in NaCl Soln.
 447    Calcium Sulfate (Gypsum) Solubility in NaCl Soln.
 448    Calcium Sulfate (Gypsum) Solubility in H+/Na+/ClO4-
 449    Calcium Sulfate (Gypsum) Solubility in NaCl Soln.
 454    Calcium Sulfate (Gypsum) Solubility in H+/ClO4- Soln.
 463    Calcium Sulfate (Gypsum) + Potassium Sulfate Solubil.
 464    Calcium Sulfate (Gypsum) + Potassium Sulfate Solubil.
 465    Calcium Sulfate (Gypsum) + Potassium Sulfate Solubil.
 466    Calcium Sulfate (Gypsum) + Potassium Sulfate Solubil.
 467    Potassium Sulfate - Calcium Sulfate (Gypsum) - Water
 479    Calcium Sulfate (Gypsum) Solubility in Water
```

- Then have your selected set of data displayed

```
SOL Command (H,L,Q,S,U,V) <L> : V

TXT file name OR dataset number : 435

Dataset 435
Calcium Sulfate (Gypsum) Solubility in MgCl2  [24192]
Analytes = Ca+2_SO4-2 + Mg+2_Cl-1(2)
VBS = Cl-1 + Ca+2 + SO4-2 + Mg+2
Wgt = 5p   Press. = 1.0 (atm)    Temp. = 35.0 (C)

CACLMG   Conc1   Conc2   ADens.  FIZ_DA  FIZ_SV  FIZ_KY  Phase
  line    (m)     (m)
   38    0.0551   0.34   1.030*  1030.   1564.   397.3   Ca+2_SO4-2_H2O(2)_(s)
   39    0.0611   0.68   1.053*  1053.   1594.   374.1   Ca+2_SO4-2_H2O(2)_(s)
```

'[24192]' gives the JLR literature reference number of the data source.

'Analytes' refer to the chemical entities whose total concentrations determine the composition of the solution.

'VBS' refers to the 'Variable Basis Species' which should be used as a basis set for calculating the chemical speciation of the solution.

'CACLMG' is the name of the text file containing this set of data.

'ADens' refers to the 'Analytical Density' - the solution density used to convert concentration units (generally at room temperature).

The 'FIZ' quantities refer to the solution density (DA), the velocity of sound (SV) and the isentropic compressibility (KY) *under the specified conditions*.

THE UNIVERSAL DATASET

This document describes how to access the information in the JESS Universal Dataset, called 'UDS'. The aim of UDS is to provide a single mechanism by which all JESS data can be inspected and retrieved, regardless of its originating JESS database. By combining the reaction parameters of JPD with the physicochemical values of FIZ and SOL, it provides a single place to search for data from given substances, given reactions, given properties, given literature references and given combinations thereof. UDS is central in our effort to develop a better approach to the parameterisation of chemical speciation models.

INTRODUCTION TO UDS

One of the most frequent uses of UDS is to determine if there are data anywhere in JESS from a particular given literature reference. This is straightforward and needs little explanation – just follow the VEWUDS prompts, entering 'Locate', then selecting option 3 and supplying a JLR accession reference number.

In essence, otherwise, there two ways of using UDS: you can either enter a one-off set of criteria or, for more advanced purposes, you can build a so-called 'profile' of search options comprising elements, primitives, basis species, any species, literature references, chemical reactions, ranges of pressure, temperature and ionic strength, etc. Profiles are re-usable so they can be tried, adjusted and tried again, as often as necessary.

> "Can it be, Sir, that a misprint even in dog-Greek can now pass undetected …?"
>
> W. McG Eagar
> *In 'The First Cuckoo', Letters to **The Times** 1900-1975, George Allen & Unwin Ltd. (1976) p. 138.*

USING PROGRAM VEWUDS

This program provides the so-called 'read-only' facilities of the UDS package, *i.e.* it enables you to examine and to search for references, but not to do anything that alters the database.

The program is command-driven, meaning that it expects you to enter one of several instructions, indicating what you wish to do. The prompt which is displayed when the program is waiting for one of these commands looks like this.

UDS Command (H,L,Q,R,S,V) <V> :

In response, you can choose to enter any of the commands discussed below. Each of them can be shortened to their initial letter. The letter shown on the prompt between angle-brackets (which, during the session, is usually the previous command entered) is the default command, *i.e.* it is selected simply by pressing the |ENTER| key.

Generally, when the execution of a command is completed (or is terminated prematurely by you), the program will re-issue the UDS Command prompt, indicating that it awaits a new instruction. Otherwise you can return to the UDS Command prompt by entering **Quit** or **Q** at any time.

COMMANDS

HELP

This causes the program to display the list of valid commands. The facility is only an 'aide-memoire'.

QUIT

This tells the program that you wish to terminate the present session. The program requests confirmation of this. Simply pressing |ENTER| (to implement the default **Yes** response) causes the program to halt.

VIEW

All the details in the database associated with each reference can be displayed. The **V**iew command enables you to select datasets by specifying their identifier (see below). You will generally need to find the dataset you want by using the **Locate** command described next.

When you are finished with VIEW, type **Q** for **Quit** to return to the UDS command prompt.

LOCATE

The **L**ocate command enables you to search for those datasets in the database associated with particular elements, physicochemical property, keyword, JTH primitive symbol, JTH species or literature reference.

When you are finished with LOCATE, type **Q** for **Quit** to return to the UDS command prompt.

SIZE

The **S**ize command displays the current UDS database statistics.

REDO

The **R**edo command displays again data matching the existing profile.

When you are finished with REDO, type **Q** for **Quit** to return to the UDS command prompt.

A WORKED EXAMPLE

Only the simpler, one-off search is covered in the following worked example. Once you have that hang of this, select VEWUDS 'Locate' option 1 and build up a more complicated profile of search criteria. Here again, the key is to explore adventurously.

• Execute program VEWUDS. It should respond (more or less) as follows.

```
VEWUDS (Version 8.7) JESS copyright (C) 1985-2019
Licensee : Peter May, Murdoch University, Australia
Welcome. Sunday, 10-Dec-19 21:22
```

• Begin by searching for some data

```
UDS Command (H,L,Q,R,S,V) <V> : L

Select one of the following search options

    1.  Data sets matching a profile of re-usable criteria you build
    2.  Data sets selected by a linear filter you define in one pass
    3.  Data sets with a given literature reference
    4.  Data sets with a given chemical reaction

Select one (1-4) <2> : |ENTER|

Species : Ca+2_SO4-2_H2O(2)_(s)

```

FILE MANAGEMENT

This document outlines what you need to know about managing your computer files **before** you perform a JESS equilibrium calculation. You'll need to be familiar with the details provided here when you start your chemical modelling.

For various reasons, it is desirable to put the data needed for your modelling into your own area (or 'directory' or 'folder'), separate from the main JESS databases. Most importantly, this gives you freedom in carrying out your calculations but there are other advantages as well, such as speeding up your work and isolating the JESS databases from the vagaries of particular models (and modellers!).

Once upon a time
the value of a program
used to be proportional
to the weight of its output.

Nowadays, the problem is how to
manage the 'infoglut'.

Inevitably, though, there is a price to pay for this autonomy. It is, in essence, that you must learn to manipulate your own data. This means familiarizing yourself with the operating system of your computer and learning how to manage the (many) files which are produced by JESS when an equilibrium calculation is performed.

BASIC OPERATING SYSTEM COMMANDS

You do not need an advanced knowledge of your computer's operating system as it works in a DOS-Window, but you must at least be able to perform the following basic operations.

- set up a new subdirectory (DOS command = **md**)

- move around your directory structure (DOS command = **cd**)

- copy files (DOS command = **copy**)

- delete files (DOS command = **del**)

Beginners should also familiarize themselves with the use of 'wildcard' commands as soon as possible. These can save a lot of time and help to prevent errors. An example appears below.

CONVENIENT JESS ABBREVIATIONS

A standard set of three-letter abbreviations exists for users of JESS under all operating systems. These should have been set up as part of the JESS installation procedure.

The abbreviations are for standard commands you can enter at the operating system prompt (*i.e.* not whilst a JESS program is running).

You should try several of the commands to test that the JESS environment has been activated on your computer. They are as follows.

dir	-	list files in your current directory / folder
jed	-	activate the JESS editor
sdd	-	move between JESS-specific directories / folders (a letter is specified, separated from **sdd** by a space)
shd	-	show current (default) working directory
xqt	-	execute JESS program (the program name is specified, separated from **xqt** by a space)

There are also DOS abbreviations for the main JESS directories / folders, each of which has a name commencing with a letter from a:z (but omitting 'y'). These abbreviations take the form of '%j?%' (without the quotes) where '?' is the unique initial lower-case letter of the directory/folder name. For example, you can make a copy to your current working directory of the JESS reaction database called 'JPD' which is held in '..\VEWDTA' as follows.

copy %jv%\JPD*.IND .

The final dot in the above command tells DOS to copy the files into your current location. It is good practice to make a copy of JPD each time before you modify it using program UPDJTH. When you are finished (and have updated JPD using program UPDUCC), you copy the files back to '..\VEWDTA' as follows.

**copy JPD*.IND %jv% **

Since you want to overwrite the old database in '..\VEWDTA' with your new one, you respond to the DOS query by typing **a** (for 'all').

This procedure is used to ensure that you can recover easily if anything goes wrong while you are changing the database. There are several ways to deal with such problems (described by program HELPER) but if you haven't made too many modifications in your current session the easiest is just to delete the corrupted files and start again.

STRUCTURING YOUR DATA

It is difficult to overstate the importance of properly organizing data on computers. This very much applies to your JESS data, where you'll find that all the thought and care that you put into establishing a systematic structure will be amply rewarded in the long run.

Individual requirements differ considerably so we cannot recommend a single approach that will suit everyone. However, you should think in terms of the number of projects in which speciation calculations may be required and the number of different contexts within each project that you may wish to model. It is generally wise to structure your data accordingly, having a separate directory (folder) for each project and separate sub-directories for each major kind of model. Disk capacity is cheap enough so you generally should not worry about a proliferation of stored models. Much more critical will be your ability to organise them and name their storage places meaningfully (so you can easily find them again later on).

If you are a beginner, you should simply create a single directory space (folder) in which you can practice. It is a relatively simple matter to start each modelling exercise from scratch, by deleting the files created previously. On the other hand, when you get going in a serious vein, you'll find that there are considerable advantages in preserving the data created during your modelling for future reference.
TEXT EDITING

This document outlines what you need to know about editing text **before** you perform a JESS equilibrium calculation. When you start your chemical modelling, you'll need to be familiar with the editing conventions described here in order to control your calculations and to modify their input.

MODIFYING DATA

Although JESS attempts to make the preparation of your input data as straightforward as possible through the use of menus and pre-set sequences of prompts, we have learnt that there is a limit to the usefulness of such methods. In particular, when you need to modify your input data (as opposed to preparing it initially) there are just too many possibilities to deal with conveniently by question and answer.

For this reason, we employ a mixed approach, in which changes are made by you using a generalized editing facility (as well as by providing appropriate responses to programmed questions and by selecting between available options).

> "Practice yourself, for heaven's sake, in little things; and thence proceed to the greater."
>
> *Epictetus* (quoted by Donald Knuth in 'The Art of Computer Programming')

How you go about making changes using the generalized editor is the subject of this document. You will find the need arises in many different contexts within JESS. Indeed, we consider the widespread use of the same editing conventions throughout JESS as a key part of our development of a consistent and user-friendly interface. It follows that you should familiarize yourself with the basic methods for editing data.

You do not need to master all the facilities that are available but it would be unwise to proceed without being able to make simple changes with confidence. In this respect, *practice makes perfect*.

The easiest way to practice your editing skills is to use the JESS editor called **jed**. Although you will not generally use the **jed** program itself during your modelling activities, you will often find yourself in identical editing environments to those supported by **jed**. You need to be able to recognize these various environments so that you can operate appropriately.

A WORKED EXAMPLE

You should begin by working in an empty directory space. Using **jed** you should create a file with some arbitrary lines of text. Then practice making a selection of changes. Following the instructions below, try to insert new lines of text, copy and delete them; also, make some specific changes to existing lines of text (without retyping the entire line). You should take careful note of the three different modes of working which **jed** supports. If anything goes wrong and you find yourself stuck, simply delete all the files in your working directory and begin again. (This is the reason for practicing in an empty directory space to begin with!) Note, in particular, that if for some reason the temporary files created by **jed** (called jed.jnl and jed.use) are not deleted at the end of your editing session (as they should be) then you will not be able to execute jed again until they have been deleted. This is a mechanism to protect against the loss of data which may occur if there is a system failure during a prolonged editing session, but it is not something you need be concerned with as a beginner.

A BEGINNER'S GUIDE TO JED

JED, the JESS Editor, is a simple line-oriented facility for creating and modifying files. The following description briefly covers the basic operations which are available to you. Consult the JESS Users manual for a fuller account.

Activate the editor by typing (after the operating system prompt, here indicated as $)

> $ **jed**

The program will display a welcome message and then prompt for the name of your file. For example, enter

> File: **try**

Please note that under the rules for JESS filenames certain restrictions apply here. (*e.g*. casing is insignificant, the name must begin with a letter and must comprise 1-6 alphanumeric characters). Only certain file name extensions are permitted (examples of some full JESS filenames are msg**.**wrk, data**.**est, report**.**txt); under some operating systems only the first letter of the extension is used by the operating system.

If the file (try**.**wrk) exists, **jed** will load it into a working buffer and initiate its 'line-editing mode'; if not, an empty buffer will be created and your editing session will commence in 'input mode' (as described on the next page). All editing changes are made to the buffer, *i.e*. none are actually performed on the file itself until the editing session terminates (which means that your original file cannot easily be destroyed if the system crashes during the editing session).

JED operates in three main 'modes'.

1. Text-accepting or Input Mode

    This is indicated by the prompt 'Input:'. Every line is entered directly into the working buffer, as you type it. Terminate input by typing **E** (for **End**) as the only input to the prompt.

2. Line-editing mode

    This is indicated by numbers displayed in front of the lines shown on the VDU screen immediately above the 'Jed >' prompt.

    - You can relocate yourself in the file by entering any line number.

    - You can display a range of lines by entering two line numbers separated by a colon (**:**).

    - You can display all the lines in your file by entering **.:∗** where the period (**.**) stands for the first line and the asterisk (∗) stands for the last.

    - Enter a period (**.**) to move to the first line of the file; enter an asterisk (∗) to move to the last line in the file; press |ENTER| to move to the next line in the file (if there is one).

    - Enter the command **H** (for **Help**) to obtain a summary of the Jed command set. The following are those with which you should first familiarize yourself.

Advance or **A**	-	display the next screenful of lines
Back or **B**	-	move backward one line
Copy or **C**	-	copy current line
Delete or **D**	-	delete current line
Input or **I**	-	enter Text-accepting (or Input) mode
Quit or **Q**	-	terminate editing session
View or **V**	-	view a screenful of lines about the current line.

    - You can copy and delete a range of lines by following the command with two line numbers separated by a colon (**:**).

    - Insertions (*e.g.* following the copy or Input commands) are made immediately after the line at which you are currently positioned.

- You can edit individual lines to make minor changes using a set of special conventions based on characters typed immediately under the current line.

    (i)   a tilde (~) causes the character above it to be deleted

    (ii)   a circumflex (∧) causes the character above it to be blanked out

    (iii)   a solidus (|) followed by some text causes the new text to be inserted in the above line immediately in front of the character above the solidus

    (iv)   two consecutive soliduses (||) causes the remainder of the line above to be deleted, from the character above the first solidus. If the two soliduses are followed by new text this is used to replace the text that is being deleted

    and

    (v)   a backslash (\ ) causes the casing of the letter above it to be changed, *i.e.* uppercase to lowercase and *vice versa*. Non-alphabetic characters are unaffected.

- You can find specified text in your file using the **Locate** command (which can be abbreviated to **L**). For example, **L.:∗|abc|** will search through the file from the first line to the last to find the first occurrence of the character string 'abc'. Other searching capabilities are described in the JESS User's Manual.

- You can exchange occurrences of specified text in your file with other text using the **Substitute** command (which can be abbreviated to **S**). For example, **S.:∗|abc|wxyz|** will replace every occurrence of 'abc' with 'wxyz'.

- You can cancel the effect of previous commands using the **Undo** command (which can be abbreviated to **U**).

- You can terminate your editing session without having any changes implemented by entering **Q|U** (for 'Quit and Undo').

3.   Modify Mode

This is indicated by the prompt (spread over two lines) 'Mod.Cmd. > '. The lines of text are held in a special buffer and are referenced by position (*i.e*. **not** by line number).

Modify mode is commonly used by the programs that prepare input for your speciation calculations.

- Enter a period (**.**) to move to the first line in the buffer; enter an asterisk (∗) to move to the last line in the buffer; press |ENTER| to move to the next line in the buffer (if there is one).

- The commands for **Back**, **Copy**, **Delete** and **View** (without line numbers) have the name function as they do in line-editing mode.

- Lines can be edited in Modify mode using the same conventions of characters typed under the current line as described under line-editing mode.

- You can enter Modify mode from Text-accepting or Input mode by entering the command **Modify** (which can be abbreviated to **M**).

- You can enter Modify mode from line-editing mode by enter the command **Modify** followed by a two numbers separated by a colon (**:**) to indicate the range of lines that should be loaded into the modify buffer.

- You terminate Modify mode by entering the command **Quit** (which can be abbreviated to **Q**). To terminate modify mode without implementing any changes, enter **Q|U** (for 'Quit and Undo').

"As long as man is striving, he is in error. We can redeem whoever continues to strive."

(cited by L.G. Sillén,
Chem. Br., 1967, 3, 291)

MODELLING DESIDERATA

This document describes, in general terms, the modelling capabilities of JESS. It is intended to give you an overall perspective before you read the EQUILIBRIUM CALCULATIONS document in this Primer or plunge into the business of modelling itself.

JESS RAISON D'ETRE

JESS is a computer system for determining chemical speciation in complex aqueous environments. The JESS concept came from a union of two main ideas: first, that chemical speciation has many significant and varied applications across a wide range of scientific disciplines and, secondly, that this potential is largely unfulfilled because of certain conceptual and technical difficulties in calculating speciation distributions without error.

The reasons for these difficulties are interesting but too complicated to deal with in much detail here. Suffice it to say that problems abound which make the modelling of chemical systems highly demanding.

> "O world invisible, we view thee,
> O world intangible, we touch thee,
> O world unknowable, we know thee,
> Inapprehensible, we clutch thee!"
>
> *The Kingdom of God*
> by Francis Thompson (1859-1907)

Indeed, to determine correctly any but the simplest of speciation distributions requires an almost superhuman combination of expertise, judgement and carefulness (see J. Chem. Eng. Data, 2001, 46, 1035 and Appl. Geochem., 2015, 55, 3 for example). It is therefore not surprising to find that many chemical models published in the literature are seriously flawed.

JESS is the outcome of an international effort to investigate and, if possible, to solve this problem. The founding concept was to exploit progress in computer technology, especially the well-known but still spectacular improvements in hardware power and software methodology. Many of our worries associated with chemical speciation modelling seemed amenable to a new computer-based approach. This remains as true now as it was then. Our ongoing aim is to exploit the exactness and consistency of the computer and also to use the fact that much (if not all) of the necessary specialized knowledge could be encoded, so that some artificial intelligence can be called upon to assist during the calculations. (Computers don't make misteaks!)

Modelling Desiderata 2

Significant progress has been made in the development of JESS since its inception in 1985. It has grown into a large software package with various advanced modelling facilities. It is unlike any other computer code for equilibrium calculations. Some of the more important differences are described below. In general, however, JESS is very much concerned with the assumptions that such calculations always involve and how errors in thermodynamic data propagate. This means that it exposes you to issues which are often otherwise concealed. You will find that this is not always a comfortable experience!

You should thus regard JESS as a powerful research tool for investigating chemical speciation in complex environments (rather than as just a means of obtaining equilibrium distributions). If you have a single application, as opposed to a broader interest in the computer simulation of equilibria in solution, you should probably NOT attempt to use JESS yourself. Ask one of us, the JESS authors, to help you.

The remainder of this document assumes that you are a determined practitioner of chemical speciation modelling (or wish to become one)! This focus on modelling (as opposed to the straightforward calculation of speciation distributions) is tackled using the facilities we call the 'GEM Stages' (see Primer Document 11 and also May, P.M. Appl. Geochem., 2015, 55, 3 (which gives many operational details). Note, before going further, that if you are sure about the chemical species you want to consider and know exactly what equilibrium constants you want to use, you do not need the GEM Stages – use ESTA instead – but, please, be aware of the general pitfalls that plague this approach. It is well to remember Tukey's Principle, given in Primer Document 1 (APPROACHING JESS).

VIVE LA DIFFERENCE

The approach taken by JESS towards equilibrium modelling in the GEM Stages is distinctive in several major respects.

1. Thermodynamic parameters appear in the database just as they appear in the literature, *i.e.* generally in their raw form, without omission of redundancies or inconsistencies and without any transformation of the data.

2. The procedure involves many independent computer programs.

3. Reactions (and their equilibrium constants) are represented in different ways at different stages in the procedure. The transformations to achieve this are carried out automatically.

4. The effects of kinetics on equilibrium calculations (metastability in particular) are more easily handled and are kept explicit.

5. Theoretical corrections for changes in ionic strength and temperature are minimized. The semi-empirical functions used for such purposes are also known to work reliably for many types of reaction and over wide ranges of conditions (temperatures up to 250°C and ionic strengths up to 5 M); however, errors in the available thermodynamic data are often limiting so it is important to control their propagation as much as possible.

6. Large numbers of equilibrium calculations can be conveniently performed, *e.g.* as required in the production of graphical output or in kinetic simulations.

You need to understand these issues, to some extent at least, to appreciate what JESS does. You will encounter them shortly after you commence using JESS for modelling purposes. They are likely to prompt you to ask the following kinds of question.

● ***Why do redundant, inconsistent and incorrect data appear in the JESS Parent Database?***

In compiling any database that is thermodynamically consistent it is necessary to make a large number of assumptions about the purpose of the intended equilibrium calculation. These assumptions relate not only to the 'domain' of the model (*i.e.* the range of conditions which determine the suitability of data and influence their selection) but also to the appropriateness of some of the chemical relationships. Typically, literature data are transformed to accord with some pre-determined set of 'components'. Unfortunately, these choices are frequently arbitrary and, inevitably, they restrict the type of calculation for which the database will be suitable. A major problem is that, early on, these assumptions tend to be rather poorly formulated and, later on, they tend to get forgotten.

By including data in the Parent Database exactly as it appears in the literature (warts and all!) JESS retains flexibility. The processes by which consistency is achieved are automated and thus remain under your control. In particular, this gives JESS models a unique reproducibility as well as allowing you readily to explore the consequences of different choices of criteria. The approach also makes errors easier to avoid and easier to detect.

A major part of the work done for equilibrium modelling purposes by JESS arises directly from the need to sort out incompatibilities in the literature data and then to select thermodynamic constants using a well-defined algorithm. This is the price that has to be paid to avoid the errors and hidden assumptions which are inevitable in the alternate approach, *i.e.* transforming data during database compilation to accord with a pre-determined modelling domain (especially 'master species').

It is also worth focussing here on another advantage of the JESS methodology. 'Bad' values are, intentionally, included in the JESS Parent Database. Although not of primary importance, this is useful because less time gets wasted on constants in the literature that are hopelessly incorrect. Otherwise, if they are not properly recorded, they tend to be re-examined, time and again. JESS has a system in which all thermodynamic values are assessed during database compilation and assigned a 'weight'. These weights indicate our best assessment of the reliability of each value. Every constant we consider 'worthless' is given zero weight and thus has no influence on subsequent calculations.

● ***Why does JESS initially require so little input from me?***

To lighten things up, we will start this explanation with some doggerel:

Even experts forget what once used to flow,
and can't well recall it, given only a mo;
But YOU haven't a clue, what you need to know,
and sure cannot learn it, all in one go!
Banal as you may find this, it succinctly describes two important pillars of JESS philosophy. First, as described above, most equilibrium calculations depend on a large number of chemical and computational decisions. Secondly, you are unlikely to be aware of all the factors on which these decisions ought to be based, *especially initially*. Hence, it is difficult for inexpert users to specify precisely how to model the chemical system of interest to them. Instead, this expertise must be provided by JESS, with the computer making whatever choices seem best to suit your circumstances. (In this sense, every 'expert system' necessarily has to be something of a black box.)

Of course, we (the developers of JESS) do not want the criteria used by our software to remain forever hidden from you. On the contrary, we believe that equilibrium calculations in which the methods and assumptions have not all been made absolutely explicit should be firmly rejected. Indeed, you will find yourself frustrated from time to time when JESS faithfully reminds you of the effects of some earlier decision you have made (or was made for you)! As tedious as this may seem when it happens, it is better than the alternatives - hiding or ignoring these decisive issues.

To us, then, the matter is simply one of order: if JESS can produce results by making as many sensible decisions itself as possible, you can *initially* restrict yourself only to those which are critical to your application. In most cases, these specific issues will be relatively few in number and, even more to the point, are most likely to come into focus only when you inspect the results of your modelling. You are then in the best position to consider the decisions that led to your particular outcome. Typically, you will wish to change one or more of them and redo your calculation. How you go about making such changes is described next and in the EQUILIBRIUM CALCULATIONS document.

- ### *Why are so many computer programs needed for an equilibrium calculation?*

All equilibrium calculations performed by JESS are divided into a sequence of small(ish) steps. Each step is implemented by a separate program and each step also has programs dealing with input and output at that step.

When you wish to alter something about the calculation you just need to identify the point at which the decision in question was taken. It is then a relatively straightforward matter to change the input at that step (on which the decision was based) and to repeat the calculation *from that point onwards*.

In practice, then, you *initially* perform each of the necessary steps in your equilibrium calculation automatically. Apart from specifying some basic information about the chemical system you wish to model, you do not concern yourself with the means by which the computer makes decisions as you go. (JESS provides this input by default.) In this way, you rapidly accomplish an initial calculation and you successfully obtain a speciation distribution.

Typically, you will then notice in your results something unexpected or unwanted. For example, you may be surprised that no solids have appeared (because, by default, precipitates are not allowed to form). Taking appropriate action to correct the unsatisfactory decision(s) in the calculation sequence is much easier once you have clearly identified a *specific* issue.

Good answers are rarely obtained without going through a number of these cycles. Typically, you'll discover a variety of factors which have an important bearing on the chemical system you are modelling. It is these that are responsible for many of the difficulties with equilibrium calculations described at the start of this document. Obviously, they must be considered very carefully by you. JESS can help identify the issues but, for the most part, only you can settle them. You do this by thinking circumspectly about the chemical context of your calculation.

A key JESS facility in this regard is the record of 'methods and assumptions' which is kept at each step in the calculation sequence. You can inspect this record interactively and have it printed for posterity. Your final decisions recorded in this way (whatever they may be) should be retained in their entirety. This is in case the basis of your modelling needs to be re-examined later on. You will soon learn that 'posterity' often includes yourself, and 'later' may be surprisingly soon afterwards!

● *Why are kinetics involved in equilibrium calculations?*

This is perhaps the most profound problem that JESS must help you to overcome. It arises because most chemical systems regarded as being at thermodynamic equilibrium (both for the purposes of calculation and behaving as such experimentally) are actually not so.

Consider, for example, almost any organic complexing agent in a solution that is exposed to air. From experience we know that such agents may interact with metal ions in perfect accordance with the law of mass action. As long as the metal ions are not susceptible to oxidation, this observation does not in general depend on how long the solution stands. Yet there can be no doubt that many organics in contact with air are not in their most stable thermodynamic state.

Interestingly, if the thermodynamic relationships describing such a system are properly established, an equilibrium calculation will (where it should) show that $CO_2(g)$ is formed by oxidation of the organic compound. However, most experts in speciation would not set up their calculation in this way. They would be intent on describing the behaviour of the system in terms of changes in the metal ion binding, say as a function of pH. In other words, the outcome of their 'equilibrium calculation' depends on certain assumptions that they make (wittingly or unwittingly) about the kinetics of processes in their system.

This is not a trivial step to take! The identical problem crops up in many other guises, sometimes quite alarmingly. For instance, the question of how to simulate solutions containing ammonia and nitrate frequently arises for models of environmental interest. Interconversion of the two substances occurs sometimes but not always. Systems containing sulfide and sulfate provide another common example in the same vein. There are also ligands with more than one kinetically distinct binding conformation, such as thiocyanate, in which the less thermodynamically favoured arrangement may persist long enough for an equilibrium to be characterized. Likewise, Ostwald's rule of stages in crystallization (which holds that the least stable solid tends to precipitate first) has far-ranging implications for many speciation applications.

> "The rules," Ralph shouted.
> "You're breaking the rules!"
>
> "Who cares?"
>
> Ralph summoned his wits.
>
> "Because the rules are
> the only thing we've got!"
>
> *Lord of the Flies*
> by William Golding

In each of the above cases, different results will be obtained from an 'equilibrium calculation' depending on how it is set up. And, since the way it should be set up in practice lies wholly outside the realm of thermodynamics, there are no fundamental rules to guide how it should be done.

It follows that you will often want to perform 'equilibrium calculations' in a way that reflects certain non-thermodynamic constraints on the system. JESS will assist you to do this and keep track of what you've done.

We call the outcome of such calculations 'quasi-equilibrium distributions' to distinguish them from the (rather rare!) true thermodynamic result. The abbreviation QED thus appears in some important JESS contexts.

You activate the calculation of a quasi-equilibrium distribution by 'uncoupling' appropriate reactions. In effect, this imposes a kinetic constraint on the chemical system by removing the connection between species (by which elements in those species could otherwise be exchanged).

Further details on how to put all this into effect are given in the 'EQUILIBRIUM CALCULATIONS' document under the section 'Determining species basis sets (BAS Stage)'.

● *Why are the JESS corrections for ionic strength and temperature so complicated?*

The complication is more apparent than real. The thermodynamic parameters in a JESS database span a variety of conditions, including values for different solvents, background electrolytes, ionic strengths and temperatures. This is unlike other computer codes that reduce all the available data to a single value at a particular reference state (usually infinite dilution). Hence, JESS can employ values that happen to be measured more closely to the conditions of your model. Errors arising from imperfect methods of correction, such as occur with Debye-Huckel functions, are thus minimized.

For reasons of both simplicity and speed of calculation, however, it would be highly undesirable for JESS to select the values of thermodynamic constants in the manner described above during the equilibrium calculation itself. This is rather done beforehand, codifying the result and saving calculation time. For modelling in the GEM Stages, JESS determines an empirical function to describe these values and employs this during its equilibrium calculations. There are nine coefficients in the empirical function used by JESS; we call these the 'Unconditional Correction Coefficients' or UCCs. You should note that our UCCs do not refer specifically to the range of conditions relevant to your modelling. They are based on values from the database under all conditions for which the reaction has been characterised. In this sense, UCCs differ from the CCC functions used in earlier versions of JESS (see May PM and Murray K, Part III, *Talanta*, 1993, 40,

819). The current basis for UCCs has been described in the literature (see May PM, *Chem. Commun.*, 2000, 1265).

● *How does JESS approach the issue of specific ion interactions?*

Since the 'ion association' (speciation) models developed during the GEM stages use conditional equilibrium constants which are functions only of temperature and ionic strength (i.e. they do not include effects from so-called specific ion interactions), a well-defined strategy is needed to deal with observed differences in the corresponding equilibrium constants (lgKs) as stored in the JPD reaction database. An important issue in this context is that experimental and other errors in lgK are often as large, or larger, than any actual specific ion effect and there is, in general, no way to distinguish which is which.

Assuming that the weighting of JPD lgKs has eliminated those which are evidently wrong, the optimisation of thermodynamic reaction parameters must serve two distinct purposes: (a) for use in GEM stage calculations but also (b) for direct JPD reference purposes, for extrapolation back to infinite dilution and for the maintenance of internal consistency by automatic comparison and other procedures. In the case of (a), specific ion effects are necessarily neglected but this would obviously be inappropriate in the case of (b) where a pattern of differences between background electrolytes is often clearly discernible. We try to resolve these two opposed requirements as follows, all the time seeking to maximise the information content available for modelling calculations.

1. When the lgKs available for a given reaction do not allow distinctions by background electrolyte, either because the measured differences between background electrolytes are too small or because there are just too few constants available, the fewest adjustable reaction parameters are employed to achieve a satisfactory fit by expressly excluding any specific-ion coefficients. This hinges on the notion that most lgKs are determined in supporting electrolyte solutions chosen by the investigators to be 'inert'. In essence, all effects on lgK are then attributed only to the *ionic strength* of the supporting electrolyte medium.

2. Specific-ion coefficients are introduced when, and only when, lgKs *of good standing* for different background electrolyte solutions are found to differ significantly. By preference, such effects are attributed to the relevant ions in the order $Li^+ > Na^+ > K^+$, Rb^+, Cs^+; however, they can also be attributed to Cl^- when this is in accord with generally-expected chemical behaviour or to K^+, Rb^+, Cs^+ ahead of Li^+ or Na^+ in certain exceptional circumstances. The key concept here is that the UCC parameters other than the specific-ion coefficients (reflecting the average effect of ionic strength) ought to represent what happens *on average* in an 'inert' or 'indifferent' electrolyte medium, which is the most suitable for GEM Stages modelling.

For example, when a lgK is measured in NaCl(aq): (i) the lgK will be used as such if there are no other lgKs available in other background electrolytes; (ii) the lgK will be included in an averaging process if there are data in other background electrolytes which are **not** deemed to be systematically different; (iii) the lgK will be fitted with an adjustable Na-specific coefficient if there are data in other background electrolytes which are deemed to be systematically different; and (iv) the lgK will be fitted with an adjustable Cl-specific coefficient if the metal ion in the reaction is known to be bound (co-ordinated) by chloride to some pronounced extent (such as Hg^{2+}). Of course, (iv) is very rarely needed.

Finally, we are currently developinf additional modelling facilities which will include specific ion interactions as required by more precise thermodynamic modelling exercises. This work is well underway but not yet sufficiently ready to be released.

● ***Why does JESS use secondary sources of data?***

A tenet in critical evaluation of thermodynamic data is to use only (the best) *primary* sources of (experimentally measured) data. To do otherwise contaminates the critical evaluation with inputs that are outside the control and selection criteria of the evaluation process as well as duplicating certain original (often unknown) measurements. From a statistical perspective, in the analysis of random observations, this would introduce an (unacceptable) bias.

Why, then, are values from secondary sources included in the JESS databases and used in our regressions to obtain parameters for our thermodynamic modelling functions?

As described below, there are numerous inter-locking reasons but the first and perhaps the most important is that we, the developers of JESS, are not in the business of critical evaluation as carried out by institutions like CODATA, the erstwhile U.S. National Bureau of Standards (NBS), its successor, the U.S. National Institute of Standards and Technology (NIST), the International Union of Pure and Applied Chemistry (IUPAC) or the OECD Nuclear Energy Agency (NEA). These bodies have the people and financial resources required to make serious and regular contributions in critical assessment and harmonisation of thermodynamic data involving large teams of experts.

Obviously, we have nothing comparable but, even if we had, **our purpose is different**. Critical evaluations are necessarily always well-focussed, and therefore of limited, scope. JESS, on the other hand, aims to be as general as possible, with the widest possible coverage of inputs relevant to the modelling of chemical speciation in aqueous solution. We need often to deal with data of dubious quality (because there is no other experimental information available). We need also to deal with all sorts of applications, many of which go well beyond the coverage of even those authoritative institutions listed above. In other words, our goal demands not only a full breadth of chemical systems but also questionable data, which is a difficult domain (but necessary from a modelling perspective). For the sake of practicality, conventional critical evaluations of thermodynamic data must be purposefully circumscribed in both of these respects. Their coverage as a result is far too restricted for our modelling endeavour. We want JESS to deal with problematic, unreconciled and poorly determined systems <u>when there is no alternative</u> so that we can explore what has been reported in the literature and make modelling judgements accordingly. We want, certainly, to model those systems that are well characterised but we surely cannot be confined to them.

Excluding everything except measurements that have been made often by independent observers would leave us with precious little. This is amply demonstrated by the limited set of species available from CODATA and the feeble number of practical applications that can be tackled with CODATA parameters. Thus, JESS aims to exploit the highly commendable efforts made by experts in critical thermodynamic evaluation, not to emulate them. In compiling our databases we ask whether a given datum in the literature is one that modellers should be aware of, and should make use of when appropriate.

How best to use the information in the literature for modelling purposes is, accordingly, the main issue for us. This is a profound problem and one that JESS has only just started to address.

Nevertheless, a number of guiding principles have emerged and are being implemented. A key concept comes by analogy from signal processing: we seek to maximize 'information content' and to minimize 'noise'. It follows that we should include all data that we judge to be 'reliable' and exclude, following specific identification, only those values that would undoubtedly detract from the overall knowledge base. This means that modellers work with a dataset which is essentially uncensored by us. The onus is on **you** to perform your modelling sensibly and to make careful judgements about the reliability of your results. JESS supports many mechanisms enabling you to reconnoitre chemical systems of interest, to make your modelling assumptions and to tailor the calculation to suit your judgement and objectives.

In this context, it can hardly be doubted that the inclusion in JESS databases of parameters and other quantities derived by experts through critical review must add to the combined stock of JESS information content. It is important to remember the mechanisms that are everywhere embedded in JESS to resolve discrepancies and to produce thermodynamic consistency. These mechanisms mean that small differences (generally in the order of magnitude attributable to data uncertainty) do not impact adversely on the precision of speciation and other calculations. In other words, the errors appearing in the thermodynamic calculations reflect basic deficiencies in the literature rather than arising from our use of disparate sources. It is the task of the database compilers to ensure that gross conflicts in the data are not left unattended (because they would then propagate as vague and possibly serious errors into subsequent calculations, usually after averaging). However, as long as individual inputs are free from such major inconsistencies, and the remaining data have all been assessed as 'good', it is reasonable to think this strategy will progressively strengthen the 'signal' and generally reduce the 'noise'.

This approach utilises the JESS system in which we, the JESS developers, assign to every literature datum a so-called 'Weight'. This Weight is an integer in the range of 0 – 9. Data that are deemed to be inconsistent with better values get a Weight = 0 as described above. This means that they are ignored for parameterisation purposes. The more reliable we judge a literature value to be, the larger the Weight that it gets. Values from highly authoritative sources such as IUPAC and NEA reviews get high weights, often (say) given a Weight = 7. This signals that the value in question has a high information content and causes that value to be magnified numerically in subsequent regression processes. In this way, critical assessments published by reputable experts come to dominate values with lesser credentials.

However, it is important to note that <u>Weights are downgraded when subsequent work casts doubt on existing data and provides a replacement in which we have more confidence</u>. Such re-weightings, of course, permit the database to evolve – hopefully, improving in a progressive and sustainable manner. This cannot guarantee there will never be any dramatic changes but the process does help to smooth out their impact.

Most pertinently, Weights are downgraded when improved values are obtained in the thermodynamic harmonisation process from linear combinations of better-characterised reactions. We then introduce the improved value and reduce to zero the Weights of all other data (under the same conditions). The substituted value is given a Weight = 1 and flagged in the Thermodynamic Reaction Database by the technique 'ELC' standing for 'estimated by linear combination'. The overall effect of this strategy is to take redundant reactions out of the ongoing optimisation of reaction parameters. Values *for these redundant reactions* coming from secondary sources are thus typically prevented from having any misleading consequences whatsoever. Retaining them in the database with Weight = 0, however, allows them to be readily compared with the prevailing JESS best estimate. Such comparisons are generally interesting and often salutary.
There are some other non-trivial considerations also to bear in mind. The notion that critical assessments of thermodynamic data can be made from original experimental observations with complete purity is a myth. Thermodynamic quantities reported in the literature are, almost without exception, intermediate in the sense that they are derived through some calculation or other which depends not just on the number actually being measured. For example, solution densities are measured by vibrating-tube densitometers in the form of frequencies which must transformed into the required quantity using a calibration model and much besides. One of the biggest problems in thermodynamics comes from the errors embedded in subsidiary data that are employed in most physicochemical evaluations *per force*. Think about past changes in temperature scales, molecular masses and unit conversion scales as extreme cases in point. Eliminating all such sources of (systematic) error is typically precluded by enormous cost. Agencies like the NBS and the NEA sometimes make valiant efforts to escape such problems but with a net result that illustrates all to sharply the limitations of such approaches from a modelling perspective: not only is the scope of such Herculean operations curtailed as discussed above but the task is also never-ending, as experience clearly reveals. Today's authoritative compilation is tomorrow's imperfect source (no matter how impressive it may still appear to be). Witness the cycle of revised parameters issued as part of the NEA 'Chemical Thermodynamics (TDB) Series' as 'Subsidiary Data'.

These remarks should not be taken in any way as disparaging of the NEA or other works of such quality; we judge these efforts to be about 'as good as it ever gets'. We caution only that for aquatic modelling purposes they not be regarded as 'gospel'. Like the models themselves, they should be used, not believed. And, to prevent carving-in-stone just a single view, software packages like JESS need to treat such sources as excellent supplementary material rather than as an exclusive font of knowledge.

To illustrate this point, we can do no better than quote from the OECD Chemical Thermodynamics Series on Iron, Volume 13a, 2013, p. 90. It refers to how the Gibbs energy of formation for $Fe+2$ (no less) is established, arguing in support of a 30 mV shift from the long-established value.

> "Heusler [1982HEU], and Heusler and Lorenz [1985HEU/LOR] reviewed the value of the $Fe_{2+}/Fe(0)$ standard potential in chapters of two books, and the work of Hurlen was discussed specifically in the second review. They considered that the values of the standard potentials derived from the investigations in both chloride and sulfate solutions contain systematic errors due to junction potentials and improper estimation of the activity coefficients. For the chloride solutions we do not consider that such errors are responsible for the large difference between the standard potential recommended in established tables (–0.440 V) [1952LAT], [1985BAR/PAR] and the value found by Hurlen (–0.470 V)). The overall junction potential is presumably very small because of the cell design with two calomel electrodes immersed in the same solution. The evaluation of the activity coefficient has been done using two models, and our application of the SIT method did not yield very different Fe^{2+} activity values. Thus, the work of Hurlen seems convincing, and in reviewing it we have applied the SIT formalism to his experimental results."

This is quite typical of the machinations which all good critical reviews of thermodynamic data unavoidably undertake, although not all are perhaps so momentous. While it seems eminently likely that the expert reviewers have done the best they can under the circumstances, their job nevertheless involves both subjectivity and assumption. So, it seems to us, we are not mistaken in using this specialist opinion to inform JESS modelling. On the other hand, we think it *would* be a mistake to treat the result as if it were perfect. Only diamonds are forever.

Have no fear of perfection – you'll never reach it.

- Salvador Dali

Image follows socialdigital.dundee.ac.uk

JESS indeed does many unusual, even strange, things. These may be unconventional but, we hope, they have not been done unthinkingly. If they prove to be wrong, we will try to change them. Our philosophy is one of 'constant improvement'. As with all iterative methods, convergence depends on a good initial approximation, an effective hill-climbing algorithm and reasonable tolerances!

Automating the processes of JESS as much as practicable will certainly help in this optimisation. As to the rest, we shall wait and see.

EQUILIBRIUM CALCULATIONS

Equilibrium calculations are often thought to be straightforward by those not closely enough concerned with them! In fact, many difficulties arise as discussed above. These often confound even the experts in speciation and thermodynamic modelling (see, for example, Part I, May PM and Murray K, *Talanta,* 1991, 38, 1409). JESS was intended to deal specifically with these problems, allowing users to determine speciation distributions easily, efficiently and reproducibly. Above all, our objective is to eliminate progressively the various sources of error which always seem to impact on the traditional methods of calculation.

To achieve this goal it is obviously necessary for us to have a simple user interface, even though the underlying decision-making process is very complicated. We have thus implemented the approach described above which initially requires as little input from you as possible. You need to provide only the barest minimum of information about the chemical composition of your system. JESS provides the rest as default input. When you begin using JESS you will tend to change these defaults only when it becomes apparent that they are not what you want. As your experience grows, however, you'll probably find a mixed mode of operation most convenient, *i.e.* specifying the more obvious input parameters in advance (only if this is required by your model, of course!) and attending later to any matters that you initially overlooked or which have arisen unexpectedly from the outcome of your calculation.

There are five steps in the sequence that comprises a JESS equilibrium calculation. We call these 'the GEM stages'. GEM stands for 'Generalized Equilibrium Modelling'. Everything that needs to be done to yield a speciation distribution and to formulate the kind of output you require is included. All you have to do is to execute the sequence of GEM programs, as described in the document on EQUILIBRIUM CALCULATIONS.

JESS 'MINI-MODELS'

The capabilities of the GEM (Generalized Equilibrium Modelling) interface described in the preceding section have been accomplished at the cost of speed. Those familiar with other computer programs that perform speciation calculations may well feel that the JESS approach takes longer

and is rather more involved. This is the price that must be paid for having a database that represents the thermodynamic literature in its original, raw state as described above.

Fortunately, once the difficulties of constructing a chemical speciation model have been overcome, JESS makes it possible to abstract the specific equilibrium calculation. Thereafter, the speciation is calculated very efficiently as a function of the system's overall concentrations. This is accomplished by special programs that produce a complete, stand-alone FORTRAN code for the particular chemical equilibrium model which has been formulated. We call these FORTRAN codes JESS 'Mini-Models'.

For horrid (commercial) reasons, the means of developing 'Mini-Models' are not normally made available to general users of JESS. However, you should be aware of them so that you can ask for a 'Mini-Model' when the need arises. Perhaps the most important thing to remember is that 'Mini-Models' are application specific; all the chemical relationships (and most of the equilibrium data, at least) must be fixed in advance. On the other hand, whenever it is possible to identify a well-defined speciation calculation, a tailor-made JESS 'Mini-Model' can be constructed to provide results with exceptional speed and accuracy.

MODELLING TECHNIQUES

Chemical equilibrium models are deterministic, *i.e*. from a given starting point the outcome of the model is always the same, as predicted by the parameters and mathematical relationships of the model. For this reason, perhaps, you may be expecting to obtain one specific and quantitative answer from your modelling calculations. Sometimes it will be so, but often matters will be less clear cut than this, for a large number of reasons. What is very important for beginners to realise is that chemical equilibrium modelling generally offers you much more than a particular distribution of chemical species. To make the most of JESS you must go far beyond any single, calculated result.

Your general purpose should always be to examine the extent that different chemical models behave as reasonable representations of the real life system. Your knowledge of the real system will develop from the links that either appear or do not appear during such an investigation. We like to encapsulate the essence of this approach as follows.

"The art of scientific modelling is ...
- finding the right questions to the answers
- not being afraid to make assumptions
- getting something from nothing
- how you do it, not what you do"
All but the most trivial of equilibrium calculations entail a vast amount of information. In modelling particular equilibrium systems, you seek to understand how the chemical relationships

express themselves in a given context. You try to understand the trends involved, and to establish whether there are any unexpected trends. Indeed, this is necessary not only to extend your knowledge of the system but also to verify the equilibrium calculation.

Modellers are often warned that the results of computer models are only as good as the input (the dictum of 'Garbage in, Garbage out'). Whenever this is said the emphasis is being placed on the final single definitive answer rather than on what can be learned along the way. In fact, one often cannot answer the specific question being asked but by *finding the right questions to the information one has* one can frequently make considerable progress. This is in accord with Tukey's principle, cited in the document on APPROACHING JESS at the beginning of this Primer.

Those who criticize models on the grounds that equilibrium calculations cannot do justice to the complexity of nature are referred to the words of Iversen ('Homeostatic Regulators', 1969, G.E.W Wolstenholme and J. Knight, *eds*., p. 15) in his discussion of a model of biological control mechanisms. "On reflection it will be evident ... that a good simplification is a big advantage - as a matter of fact it is a precondition for a model being at all serviceable. If a map included all the details really present, it would be quite useless ..."

The purpose of building models, then, is not to mimic nature perfectly but rather to enable useful thinking about the system of interest. Modelling is at its most powerful when asking the questions "What happens if ..." and "What are the major factors affecting ...". We construct models because they help us to define our problems, organize our thoughts, understand our data, communicate and test that understanding and (only finally) to make quantitative predictions.

> "Predictions are very difficult …
> particularly about the future."

EQUILIBRIUM CALCULATIONS

This document outlines briefly how you perform equilibrium calculations using the 'GEM Stages' of JESS. Read it carefully **before** trying to use any of the JESS modelling programs. Only the practical procedures which you follow to obtain a speciation distribution are dealt with here; it is assumed that you understand the reasons for these procedures, given in detail in the MODELLING DESIDERATA document, which you should already have consulted. You also need to be familiar with the '**jed**' editor, as described in the TEXT EDITING document.

You will find JESS modelling unlike any that you may have experienced previously. Indeed, you should expect it to take some time to adjust. Remember that the decision-making process entailed in every equilibrium calculation is subtle and, frequently, much more complicated that it seems. JESS will guide you through these issues but, in doing so, will make a large number of assumptions about your modelling context. This is appropriate initially, whilst you are learning. However, subsequently, it is *your* responsibility to ensure that the answers you are getting in fact apply to the questions you want to ask!

"The old order changeth
yielding place to new,
And God fulfils Himself
in many ways,
Lest one good custom
should corrupt the world."

Morte d'Arthur
by Alfred Tennyson (1809-1892)

It is also important to appreciate that the description of the JESS equilibrium calculation facilities given below is not, and cannot be, comprehensive. The object for now is simply to get you going.

As and when specific issues arise during your modelling activities, you should consult the on-line documentation for more detailed information. With the programs used to prepare your input for equilibrium calculations, most prompts have additional text available describing what is required; simply type '**H**' (for **Help**) at the prompt in question to have this displayed. You can also use program HELPER to obtain advice about specific subjects (see Primer Document GETTING STARTED for details about how to use program HELPER).

THE GEM STAGES

There are five essential steps in the sequence that comprises a JESS equilibrium calculation. We call these 'the GEM stages'. GEM stands for 'Generalized Equilibrium Modelling'. Everything that needs to be done to yield a speciation distribution and to formulate the kind of output you require is included. The QED stage is the one that actually performs the equilibrium calculation. The stages before this one prepare the input for QED. **This would be a good time for you to repeat the worked example given in the Primer Document 'GETTING STARTED'**

Creating a sub-database (SUB stage)

To begin, you specify the chemical elements and/or JTH species symbols that occur in the chemical system you wish to model. The system then extracts relevant information from the main JESS database (shared by all users) and creates a sub-database for your particular application. This sub-database and all the files subsequently created are stored in your own 'directory' (folder), *i.e.* individual area on the computer. This stage is identified by the three-letter abbreviation SUB.

Specifying ranges of conditions (LGK stage)

Next, you specify the conditions which are most applicable to your modelling. This determines various priorities used by JESS and, in particular, influences which thermodynamic data are selected for your calculations. JESS then calculates the relative thermodynamic stabilities of all possible species relative to a particular set of species, known as the 'thermodynamic basis set'. You can check the output to see whether there are serious inconsistencies in the database for reactions involved in the chemical system you are modelling. Such inconsistencies have no effect on your calculations (because JESS ignores those reactions which are the least well characterised) but they serve to warn you about any unreliability of in the data available for your purposes. This stage has the abbreviation LGK.

Determining species basis sets (BAS stage)

Once a consistent set of reactions has been established and the relative thermodynamic stabilities of all species are fixed, JESS can identify what are known as the 'basis sets' of chemical species for your modelling calculations. Mathematically, elements of a set that can be combined to form all the other (remaining) elements in the set are known as a basis. Chemically, you can think of the 'basis species' as components of your system, from which all the complexes can then be formed by linear combination. You should note, however, that with some basis sets the relationship may be difficult to see. In general, especially initially, you should simply accept the basis species which JESS selects by default. The stage in which the basis species for modelling are determined has the abbreviation BAS.

Note that it is also at the BAS stage that you can impose kinetic constraints on your equilibrium calculations. This is done by re-assigning appropriate sets of species from a specified thermodynamic basis species to a species which you want to become a basis species in your modelling calculations. The effect is to express reactions for all the species in the set you specify in terms of the new BAS-stage basis species (instead of the previous LGK-stage basis species). Program TELBAS can assist you with the decision-making if your select the 'Uncoupled basis species' option under the 'Modify' command.

Performing a quasi-equilibrium calculation (QED stage)

At long last, the stage is set to perform the actual equilibrium calculation itself! In particular, the equations of your model are now ready to be constructed. These include, but are not restricted to, the mass balance equations from which the total concentrations of your system can be calculated by summing over all species. Equations imposing the solubility products of solids in equilibrium with solution and equations describing various adsorption isotherms can also be introduced.

You must specify the necessary analytical concentrations of your system and the identity of any solids which are to be explicitly included in the calculation. Solids may either be required to occur at equilibrium or allowed freely to precipitate and dissolve. A convenient mechanism also exists for carrying out repetitive calculations, in which for example particular concentration(s) are scanned over a given range. (The calculation of E_H *vs*. pH plots - or Pourbaix diagrams as they are often called - is a common requirement.) For reasons which are outlined in the MODELLING FACILITIES document, this stage (in which the speciation distribution is determined) has the abbreviation QED.

Producing output (OUT stage)

Finally, you must decide on the kind of information which you want from the calculation and the format in which it should be produced. This stage has the abbreviation OUT.

What happens at each stage

For various important reasons, every one of the above GEM stages is subdivided into several distinct operations. Each of these operations is accomplished by a separate JESS computer program. The first of these programs allows you to enter information, *i.e*. data and/or instructions, for that stage. Sometimes this information is essential, but often it is simply to change the decisions which are otherwise made by JESS. The second of these programs actually performs the task described above for the stage in question. With most of the GEM stages, a third program also exists to provide output, including a statement of the methods and assumptions that were employed in the calculations for that stage.

We use a consistent set of prefixes for the various types of computer program at each stage. The programs by which you specify input interactively have the prefix TEL; those that carry out the stage's operation have the prefix DO; and those that are used to inspect the output of the stage have the prefix VEW. Thus, the full name of each computer program comprises one of these prefixes appended by the three-letter abbreviation of the GEM stage itself.

A few of the GEM stages also have special facilities for printing their results. The programs for this have the prefix PRT.

A summary of all the programs, in the form of a Quick Reference Guide, is given on the next page.

GEM INTERFACE QUICK REFERENCE GUIDE

GEM STAGES – Generalised Equilibrium Modelling

	SUB	LGK	BAS	QED	OUT
TEL	Elements, Primitive Symbols, Source and User database, Excluded Primitives	Conditions for Maximum Reliability, Thermodynamic Basis Species Order	Uncoupled basis species lists. Excluded primitives; Included reactions. Preferred Variable and MBU Basis species	Scan info, Fixed frees and totals, Solids, P, T and I, Species to be ignored, lgK's dH's and CP's to be overridden, initial estimates, Charge balance	Determinands required as output (including those required by a future Mini-Model)
DO	Create Sub-database	Determine LGK Basis Set	Determine Variable and MBU Basis species sets	Determine Quasi-Equilibrium Distribution	Calculate values of determinands
Speed	*% (no. elements & no. primitives)*	*Fast*	*Fast*	*% (no. scan points)*	*% (no. determinands & no. scan points) and depends on type*
VEW	Sub-database statistics and primitives	Various Species Lists, Reaction Lists, Basis sets and the 'Rogues gallery'	Variable and MBU basis sets, Reactions forming species containing a specified primitive, Unconditional Correction Coefficients	Speciation, Phase distribution, Supersaturation, Partial Pressures, lgK and dH, Charge Balance, Ionic Strength, Data Quality	
PRT					Delimited ASCII files, 2-D species distributions, Contour plots

To	execute	and	and execute programs onwards from
Remove a non-basis species from the model	TELQED	select species and select 'prevent species form being considered' option	DOQED
Modify lgK of a species (directly)	TELQED	select species and specify a single overriding lgK or one/more other UCC parameters	DOQED
Modify lgK of a species (by modifying entries in the Thermodynamic Reaction Database)	UPDJTH	select database 'DBA'; change the reaction data as required; execute program UPDUCC; check UCCs are appropriately modified, *e.g.* using program UPDJTH	DOLGK
Change T and I ranges over which lgK correction functions best apply	TELLGK	modify conditions for maximum reliability	DOLGK
Remove a variable basis species from the model	TELQED	specify a log (fixed free) conc. for the species = -1000	DOQED
Add or remove solids at the QED stage	TELQED	modify the list of solids	DOQED
Apply the charge balance equation	TELQED	select 'Advanced Facilities' and invoke charge balance (also reduce by one the no. of concentrations specified)	DOQED
Override internal JESS initial estimates (*e.g.* to deal with computational overflows)	TELQED	select 'Advanced Facilities' and 'Initial Estimates' and specify required values	DOQED
Use results of a previous DOQED as initial estimates for the current run	TELQED	select 'Advanced Facilities' / 'Initial Estimates' and 'Use results of previous run'	DOQED

To illustrate how you should proceed in practice, consider the first stage (SUB).

You start by entering the information that defines the chemical system you wish to model. This is accomplished by program TELSUB, which you execute in the usual way. For example:

● Execute program TELSUB. It should respond as follows.

```
TELSUB (Version 8.7) JESS copyright (C) 1985-2019
Licensee: Murdoch University
Welcome. Tuesday, 12-Feb-19 15:50

Creating Resident Data . . .  ◄

Project  <New Project A> :  My Project

SUB Command (H,M,Q,V) <M> : M

MODIFY

      1.   Chemical Elements
      2.   Primitive Species
      3.   Advanced Facilities

Select one (1 - 3) < 1 > :  1
```

This message only appears on the first occasion, *i.e.* when your working folder (or directory) is empty.

You will then find that you are in a **jed** editing environment, and can make whatever changes to the lists of (first) chemical elements and (secondly) chemical species that you require. Remember that you terminate your editing of a list with the command **Quit**, which can be abbreviated to **Q**. This will return you to the 'Select' prompt.

Create a list of appropriate chemical elements (under option **1**). You must include **H** and **O**, these being the elements of water. You should include any other elements that occur in the chemical system of interest to you, except that **C** for carbon refers here only to inorganic species (such as carbonate). Organic species, if any, are entered next (under option **2**). These are specified by their JTH primitive species symbols. Ignore the Advanced Facilities (option **3**).

When you are satisfied that your elements and species have been listed correctly, return to the SUB Command prompt by entering **Back** or **Quit** instead of selecting a digit. You may then obtain a summary of the input that is currently to be used for the SUB stage by entering the command **View**, which can be abbreviated to **V**.

Finally, terminate execution of TELSUB (by entering **Q** and then confirming this with **Y**). That completes your contribution to the SUB stage; so, you are now ready to have your sub-database created.

- Execute program DOSUB.

After a short delay, program DOSUB should report success. You may then view a summary of what has been accomplished.

- Execute program VEWSUB.

The subsequent GEM stages all have a similar approach. However, until you gain more experience, there is no need to invoke either the TEL or the VEW programs until you reach the QED stage. The following sequence is thus sufficient.

- Execute program DOLGK.

- Execute program DOBAS.

At the QED stage, it is necessary for you to enter at least the concentrations of components in your model. Execution of TELQED is therefore mandatory. The necessary information is entered in the same sort of way as you did with TELSUB.

- Execute program TELQED.

Initially, you should restrict yourself to the simple task of specifying the concentrations required to perform a single equilibrium calculation but, later, you'll discover that by using the 'Scan facility' you can process a large equilibrium space very conveniently. The concentrations you specify fall into two categories: fixed free concentrations and total concentrations.

Usually, you will wish to have the species **H2O**, **H+1** and **e-1** in as fixed free concentrations. Note that in all contexts you are likely to be concerned with (for some while at least) unity should be specified as the concentration for **H2O**. The concentration for **H+1** is that corresponding to the solution 'pH', *i.e.* -log [H$^+$]. The concentration for **e-1** is that corresponding to the 'redox potential' of the solution, *i.e.* say -log[e$^-$] = -5 for mildly reducing conditions and +5 for mildly oxidizing conditions.

Your other basis species will generally be specified in terms of their total concentrations. Check carefully that the number of concentrations you give overall (*i.e.* as totals and as fixed frees) is the same as the number of basis species which you have. Otherwise, the equilibrium calculation will fail because the number of equations and the number of unknowns do not match.

Use the **V** (for **View**) option on the QED Command prompt to display a summary of the input you have specified and check that this seems OK before quitting TELQED.

- Execute program DOQED and VEWQED.

Follow the VEWQED procedure, just as in the worked example at the start of the Primer Document 'GETTING STARTED'

ANOTHER WORKED EXAMPLE

Here below is an exercise for you to go through. The JESS output is given in full so you can see what is being done. However, note that only a relatively few keystrokes (shown in **bold**) are required from you. This is the power of a command-driven user interface.

MODIFYING YOUR THERMODYNAMIC INPUT DATA

In the development of most models, the first calculations you perform will be based entirely on the data which comes from 'JPD', the JESS Parent Database. This information is extracted during the SUB stage, during which all the relevant data is transferred from JPD to a sub-database in your working directory (folder); this sub-database is called 'DBA' by default. It is only the contents of your sub-database that are processed by the LGK and subsequent programs.

Should you need either to introduce new thermodynamic data or to modify existing values, you do so by modifying your sub-database. For this, typically, you use program UPDJTH. You inspect the data using UPDJTH in exactly the same way as you did with program VEWJTH, as described in the THERMODYNAMIC REACTION DATABASE document of this Primer. Entering new equilibrium constants should also be relatively straightforward: simply identify the reaction in question and provide the information requested at the prompts that follow the (successive) commands 'Insert' and 'Data'. How to insert new reactions or, more problematically, new species is described in the on-line documentation which can be accessed by program HELPER; however, both of these advanced manoeuvres are probably best avoided until you have gained some experience in using JESS.

Importantly, you should note that no changes made to the sub-database take effect unless the UCCs (Unconditional Correction Coefficients) in the database are also appropriately updated. This is normally accomplished very easily - execute program UPDUCC immediately after you have completed making the modifications with program UPDJTH. Alternatively, you can optimise the UCCs from withing UPDJTH (Modify command, option 7).

In some cases, however, the automatic procedures performed by UPDUCC and/or UPDJTH will not be adequate. In particular, this may occur when the new data you introduce are very different from those for that particular reaction previously found in JPD. This is because UPDUCC does not, in general, change the set of UCC parameters used to fit the reaction's experimental data. So, for example, if new data at finite ionic strength are entered for a reaction that only used to have data at infinite dilution, your new data may not be automatically take into account in subsequent

equilibrium calculations when ionic strength corrections are required. Instead, you must do the necessary yourself, using programs EVEUCC and LODUCC. The latter provide all the flexibility needed to optimise any desired set of UCC parameters. EVEUCC does the calculation interactively and, once you are satisfied with it, allows you to write the result to an external file (usually called 'EVEUCC.WRK'). The data in this file are then loaded into your sub-database by program LODUCC. The downside of all this, of course, is that it requires you to have a good feeling for data fitting and model selection procedures.

TROUBLE SHOOTING

Although we have put considerable effort into the development of the JESS interface, trying to make it as easy to use as possible, our experience is that newcomers often encounter significant difficulties. Should this happen to you, be consoled that you are in good company!

We have identified two main reasons why these problems occur.

First and foremost, new users run into difficulties because they are not familiar enough with the basic conventions of JESS. These conventions are relatively few but, nevertheless, require some time and effort to learn. For example, you must be familiar with the ways of JTH (our Thermodynamic Reaction Database sub-system) and of JED (our general text editor) before you plunge into the GEM stages to tackle an equilibrium calculation. Despite our best efforts to keep everything as simple as possible, we have found that chemical speciation calculations (and consequently the interface needed to deal with them) cannot be reduced to triviality. On the other hand, we find that once familiar with JESS, most users come to regard it as a straightforward and convenient tool.

The second difficulty experienced by new JESS users is of a more fundamental nature. This concerns the occasional failure to converge of program DOQED when developing a new model. The reasons for this, and why we cannot cure the problem automatically, are interesting but beyond the scope of this Primer. (They stem from the enormous range of thermodynamic stability of chemical species and the limited range and precision of numbers that can be processed by computers.) What is important to you is this: a convergence failure can, to our knowledge, **always** be overcome if you manually take the necessary remedial action.

There are two main possibilities:

1. When the convergence problem arises because of an 'overflow', modify the initial estimates used by DOQED in solving the equations. This is done under the 'Advanced Facilities' option of program TELQED. Typically, you will need to identify one or more variable basis species associated with the problem and lower their initial value. You do this by using program VEWQED to inspect the results of the failed calculation and finding those species associated with a numerical overflow. The best factor to apply depends on circumstances (*e.g.* smaller reductions tend to be necessary when the chemical species concerned has high stoichiometric coefficients). Typically, -15 will suffice but sometimes -25 or even -30 will be necessary.

2. When the convergence problem arises because of an 'underflow', modify the set of variable basis species using program TELBAS. You need to find a set of basis species which at equilibrium will occur at reasonable concentrations, say above 10^{-15} M. You

can guess the likely identity of more appropriate basis species by considering the pH and E_H of the solution.

Further information about this topic can be obtained using program HELPER.

MANAGING AND PRESERVING YOUR MODELLING SCENARIOS

A key feature of JESS modelling design is that you develop each model in its own storage area ('directory' or 'folder'). It is therefore quite easy to create, use and retain separately your various modelling scenarios. It is then clearly important to keep what you have done in a form that allows you to go back and see exactly why the results turned out as they did. Every major modelling exercise requires too many chemical specifications and too many assumptions to be remembered and thus reproduced unfailingly.

On the other hand, you will likely explore many possibilities so it is impractical to record absolutely everything. To find a sensible balance, you will need to be discerning, well organised and, above all, good at record keeping. Remember also that the JPD database continues to evolve, so you cannot rely on it to provide exactly the same thermodynamic data as it did in an earlier version of JESS. This problem can be solved by preserving the DBA database in the directory/folder that stores each modelling scenario. However, there is a danger is that the DBA database may get overwritten later on by program TELSUB. You can guard against this possibility by copying DBA*.IND to DBB*.IND at the conclusion of your modelling project.

"How not to get lost in the complexities of our own making is still computing's core challenge."

Edsger Dijkstra 1990 cited in "User Interface Design" by H Thimbleby

"Things should not be multiplied without good reason."

William of Occam
14th century philosopher

WHAT ELSE?

The programs described so far in this Primer are perhaps the most important in the JESS package but they are only a few amongst hundreds. Clearly there are many applications of JESS beyond those dealt with here.

The purpose of this document is to outline some of the key remaining capabilities of JESS. By far the most numerous are the various facilities for code development. We obviously need many low-level modules for testing purposes and there is a large suite of programs to assist in producing JESS on a variety of hardware platforms. However, four other categories of JESS program are probably of greater interest to you.

> "Anyone who sits
> at the bottom of a well
> to contemplate the sky,
> will find it small."

> cited by
> J-M Lehn, Nobel Lecture, 1988

CHEMICAL REACTIONS AND THEIR LINEAR COMBINATIONS

Developing JESS has taught us many lessons about the way errors propagate in thermodynamic calculations. An important contributor in this regard is the accumulation of errors along chains of linearly-combined reactions. This may come as a surprise since you may think that just adding numbers together can be done very precisely, especially by computers. It is certainly true that the thermodynamic relationships arising in this context are strictly additive and there is no problem if thermodynamic consistency is perfectly maintained. Unfortunately, in practice, experimental error manifests itself and does so differently from one measurement to another. Thus, even the primary data are not in general thermodynamically consistent. An even bigger issue is that measurement, calculation and other errors proliferate in the recorded literature and tend to become entrenched. Thus, when working with linear combinations of chemical reactions, it is critical to select chains of reactions that are the least impacted by such errors. In particular, the accuracy of results over all reactions in the chain tend to be governed by the accuracy of the weakest link.

You can see some of these effects on speciation calculations when using the GEM Stages. More detailed analyses are also available using programs in the CMN suite (such as DOCMN, and VEWCMN).

CHEMICAL FACILITIES

These programs include CHMUTL (to convert concentration units, to provide information from the periodic table and to calculate molecular masses), FCCUTL (to calculate activity coefficients using various extended Debye-Hückel models and to correct equilibrium constants for the effects of ionic strength or temperature change), TSTH2O (to calculate various physicochemical properties of water) and PEPTID (to determine the molecular masses of peptides).

Three programs from the ESTA suite are also provided. These are ESTA0, ESTA1 and ESTA2b. They are used to process potentiometric titration data as described in the ESTA publications (ending with that in *Talanta*, 1988, 35, 933-941.)

Another small collection of code exists to facilitate the plotting of Eh-pH (Pourbaix) diagrams. Details can be found in the …\JesDoc\Manuals\Users\Useful folder.

KINETIC MODELLING

Some distributions of JESS also allow you to couple equilibrium to kinetic models. Since kinetic phenomena depend heavily on the prevailing conditions and there is no body of fundamental data equivalent to that for chemical equilibria, kinetic models tend to be much more limited than thermodynamic models in their predictive capabilities. Nevertheless, experience proves that the modelling exercise itself generally and frequently leads to new insight. This is, in part, because model development effectively imposes a structure on one's thinking. Models also help to identify the key factors amongst many which are known about the system.

JESS presently has two different kinetic facilities.

First, it is possible to set up a purely kinetic model, just based on differential equation solving. The facility is similar in concept to that provided by most conventional simulation packages - it allows you to define a set of differential equations and, given the starting values, to solve for changes occurring over time. It is called the DE (Differential Equation) interface and, like the GEM interface it involves a sequence of calculations (*ie*. the DE, DES and DEO stages). However, the DE interface can be used without reference to any chemistry.

Secondly, there is the KEM (Kinetic and Equilibrium Modelling) interface. This allows both kinetic and equilibrium processes to be modelled simultaneously. The chief advantage of this approach is that it accommodates systems with compartments in which the equilibria are too numerous or too complicated to be included directly in the differential equations being solved. Based on JESS 'Mini-Models', the KEM sub-system of JESS allows construction of models for very large and complicated chemical systems. Such capabilities are essential if we are to solve many of today's most pressing problems in applied solution chemistry. We think the potential benefits are considerable, with exciting and varied industrial, environmental and physiological potential.

Thus, in a manner analogous to the GEM stages, and following on from them, kinetic modelling is performed by JESS in three steps: DEQ (sets up a differential equation set), KEQ (builds a stand-alone executable) and KEM (solves the differential equations to determine the changes in species concentrations within specified pools over time).

Our chief hope is that, as with your GEM calculations, you will find that your kinetic modelling can also be done painlessly and without error. PLEASE NOTE HOWEVER: JESS distributions nowadays do not include the kinetic modelling facilities. Contact PMM if you want this capability.

MATHEMATICAL FACILITIES

Program MTHUTL supports a variety of numerical procedures which accept input data from the VDU. These facilities include (a) function integration, (b) function interpolation, (c) curve fitting – least squares regression and collocation, (d) equation solving – linear and non-linear functions, (e) simple statistical analysis and (f) vector and matrix algebra. Note, however, that the purpose of MTHUTL is to provide basic testing of our code, not a regular work facility.

OTHER FACILITIES

JESS also contains many facilities to assist with our everyday work on computers - too many to mention all of them here! We have our own English dictionary, spelling-checker, thesaurus manager and text formatter. We even have programs to code and decode text files for transmission across electronic networks. JESS is (so to speak) a system for all seasons - a system designed to be flexible and varied in its applications.

By now you probably think we are the world-record holders for wheel re-invention! Indeed, we are often so condemned (especially by the computer science fraternity). This is not the place to defend our policy in detail - perhaps one day, we can discuss it over coffee, or better still over something stronger! Suffice it to say that by developing a broad spectrum of facilities for ourselves we have ensured (a) that JESS can be ported readily to different computer systems, especially to those of the future, (b) that our data can be manipulated efficiently and accessed in the way we require and (c) that our system was as free as possible from various other conceivable constraints.

What in the present context seems important to us is that, whilst you familiarise yourself with JESS, you explore beyond its standard applications looking for others that may also be useful to you. We trust that, as your experience grows, you will find the system becomes progressively more powerful.

Finally, we ask you to remember that JESS is not just intended as a chemical speciation modelling facility. It is also, at its roots, a research tool for investigating better methods of thermodynamic data harmonisation. In this respect, our task is surely a never-ending one. As long as JESS continues, it will always be a work in progress. So we finish with the quotation at the start of this Primer and add three more!

"A man would accomplish nothing
if he waited till he could do it so well
that no one could find fault with it"

Cardinal John Henry Newman

"So much to do, so little done."

Cecil John Rhodes (on his deathbed)

"Yes, any fool can see what's wrong with it. Can't you see what's right with it?"

Winston Churchill

"Don't show an unfinished product to a fool!"

Kevin Murray

Good luck and 'Bon Voyage'.

THE JAM DATABASES

This document describes how to access the information in the three permanent JAM databases. Whether you are seeking thermodynamic values for substances in their standard state, or data describing how their properties change with temperature, or sets of Pitzer equation coefficients, there is a JAM database for you!

INTRODUCTION TO JAM

The databases for JESS 'algebraic models', called JAM, store a set of encoded equations that can be used to calculate thermodynamic properties of chemical substances. These substances can be pure (solids, liquids and gases) or they can be solutes in aqueous solutions (including electrolytes and ions).

Every JAM datum for a given substance is associated with a so-called 'equation subject'. Equation subjects are symbols which identify particular equation parameters.

> "[In science, change] doesn't happen as often as it should, because scientists are human and change is sometimes painful. But it happens every day. I cannot recall the last time something like that happened in politics or religion"
>
> Carl Sagan
> *CSICOP keynote address, 1987*

Typically, equation parameters can be recorded either as a single numerical value or as a function of temperature and pressure.

The three permanent JAM databases available so far are named (a) JEL for 'JESS Equation Library', (b) PTZ for Pitzer equation coefficients and (c) BEE for the parameters of our 'Primary Quantitative Framework'.

> ➢ JEL contains standard state values and data describing how properties like the heat capacity and entropy of solids change with temperature.
> ➢ PTZ contains parameters obtained from the literature for the (more-or-less) standard form of the Pitzer equations
> ➢ BEE is for parameters of a JESS model which predicts the thermodynamic properties of aqueous strong electrolyte mixtures.

Since the JAM facility allows for many different kinds of equations to be stored and used in thermodynamic calculations, the data contained in a JAM database are highly structured. You need some understanding of this structure to access the data conveniently. There are four key concepts:

1. Equations – numerical values associated with Groups and Substances for calculation in an Algebraic model.
2. Algebraic models – the theoretical framework in which such calculations are made.
3. Groups – the symbolic name given to subsets of equations indicating their source.
4. Substances – the symbolic names given to the chemical entities to which the Equation refers.

For example, two entries in the JAM database called JEL are as follows.

```
   AEM 01 : General framework : Literature standard thermo. properties
    Group : "95LiF/5-1" with Group weight = 5
    Subst. : Na+1
Eqn-Wgt. : 5
Equation : S0 = 58.45 J/(K.mol) (0.15) constant

   AEM 01 : General framework : Literature standard thermo. properties
    Group : "95LiF/5-1" with Group weight = 5
    Subst. : Cl-1
Eqn-Wgt. : 5
Equation : S0 = 56.60 J/(K.mol) (0.20) constant
```

These entries refer to the standard enthalpy, S^0, for the sodium and chloride ions respectively tabulated in Lide, CRC Handbook of Chemistry and Physics, 76th Edn., 1995, section 5, page 1.

Program VEWJAM allows you to search for data in many ways. Use the 'Locate' command to determine what Groups are available. For instance, you can list all the Groups associated with a particular Algebraic model (such as 'General framework : Literature standard thermo. Properties'). Also use the 'Locate' command to list all the Equation subject (symbols) associated with a particular Algebraic model.

Frequently one wants to inspect a set of related (parameter) values. For this purpose, JAM defines a number of so-called 'Clusters'. The 'View Cluster' command of VEWJAM displays the following options:

```
1.  Equation Subject and Group -> Substance values
2.  Substance and Group -> Equation Subject values
3.  Literature Reference -> Substances & Subjects
4.  Substance and AEM -> Subject values
5.  Group -> Summary of all values
```

Selecting option 4 and then choosing the Algebraic model 'General framework : Literature standard thermo. Properties' , Equation subject 'S0' and Chemical substance 'Na+1' yields:

```
   AEM 01 : General framework : Literature standard thermo. properties
   Subject : S0

Na+1  in 38LPS       14.0 cal/(K.mol)  (0.4)  constant
Na+1  in 95LiF/5-1   58.45 J/(K.mol)   (0.15) constant
```

Selecting option 1 and then choosing Group name '95LiF/5-1' and Equation subject 'S0' yields a long list commencing:

```
Ag+1                    73.45 J/(K.mol) (0.40)   constant
Ag+1_Cl-1_(s)           96.25 J/(K.mol) (0.20)   constant
Ag(g)                  172.997 J/(K.mol) (0.004)  constant
Ag(s)                   42.55 J/(K.mol) (0.20)   constant
Al+3                   -325 J/(K.mol) (10)   constant
Al+3_F-1(3)_(s)         66.5 J/(K.mol) (0.5)   constant
Al(g)                  164.554 J/(K.mol) (0.004)  constant
. . . .
```

Etc.

You can find <u>all</u> the Equation (values) for specified chemical substances under the command 'Locate Equation' option 1 'Specified chemical substance(s)'.

You can find <u>all</u> the Equation subjects for specified Algebraic model under the command 'Locate Subject' and then choosing the options which specify the Algebraic model you are after.

Consult the 'JAM Users Guide' in ../JesDoc/Manuals/Users/Useful for further details about JAM database, especially if you intend to enter your own data.

A WORKED EXAMPLE

Let us find the Pitzer equation parameters for NaBr(aq).

You must first establish the Equation subjects (as described above). Many possible forms of the Pitzer equations appear in the chemical literature but the most common parameters the activity coefficients of aqueous electrolytes are β^0, β^1 and C^ϕ. The JAM symbols for these Equation subjects are 'beta0G', 'beta1G' and 'CphiG' respectively.

- Execute program VEWJAM. It should respond as follows.

```
VEWJAM (Version 8.7) JESS copyright (C) 1985-2019
Licensee : Peter May, Murdoch University, Australia
Welcome. Sunday,  10-Feb-19  5:17

  You start by entering the 3-letter name of the JAM database you require.

JAM Database name : PTZ
```

- Carry out the search for the first Subject, which is 'beta0G'.

```
JAM Command (H,L,Q,V) <V> :

View Cluster, Equation, Group, Species or Reference <C> ?

You then look for the Cluster of values associated with the Subject
'beta0G' of the Pitzer framework: Miscellaneous Pitzer parameters' for the
interaction between 'Na+1' and 'Br-1'.
```

```

```

You can then establish the source of the datum, say, 0.082541 by looking up the Group, which in this case is '95YLH'.

THE FUTURE

This document describes the developments on JESS which are currently underway but not yet completed. We hope to release this work in the next year or so.

THE CURRENT STATUS OF CHEMICAL SPECIATION MODELLING

Our recent review (J. Chem. Eng. Data, 2017, 62, 2481) concludes that a number of new developments hold considerable promise but these need to be weighed against ongoing difficulties with existing theoretical modelling frameworks. Although we think JESS offers significant advantages over other chemical speciation modelling packages, it is not immune from these criticisms. The current modelling paradigm evidently has to be re-assessed, hopefully to find better ways forward, including new protocols which command sufficient support to warrant IUPAC endorsement.

"The first act is ingenious, the second beautiful, the third abominably clever."

Oscar Wilde
In conversation on 'The Importance of Being Ernest', from The Epigrams of Oscar Wilde, by Alvin Redman, 1954, p. 87.

The abundance in solution of all species must be known to calculate quantities determined by, or thermodynamically related to, $\gamma_{\pm}$. However, chemical speciation cannot be unequivocally determined without a good model for activity coefficients. It has proved impossible to escape this vicious circle without a sound *fundamental understanding* of specific ion interactions. The inadequacies of all thermodynamics modelling frameworks have not been fixed for this reason.

WHAT NEXT?

In our opinion, the present impasse can only be resolved by a fundamentally-sound single-ion activity coefficient function that couples strong electrolyte thermodynamics with weak electrolyte equilibria, allowing multicomponent systems to be modelled with confidence on the basis of reliable mixing rules and better methods of parameter estimation. Such a model should enable us to characterise weak interactions such as ion paring in strong electrolyte solutions. This will then mean we can eliminate the many spurious species that currently plague calculations when stronger equilibria are not dominant, such as seawater (see Appl. Geochem., 2015, 55, 3).

We have therefore been actively exploring better ways of dealing with activity coefficients (especially in systems where specific-ion interactions are important). However, it will take a great deal of further effort to implement fully all the modelling facilities that these improvements require. Above all, we must develop automatic procedures to determine the huge number of

function parameters which will be involved. Somewhat inevitably, it has proved necessary to change the structures of our databases, JTH in particular, which is a major undertaking now underway. Good progress has been made so we hope that the new modelling paradigm which we have been seeking is at last within reach.
